

# Kinematics

15-494 Cognitive Robotics  
David S. Touretzky &  
Ethan Tira-Thompson

Carnegie Mellon  
Spring 2013

# Outline

Kinematics is the study of how things move.

- Kinematic chains
  - Robots are described as collections of kinematic chains
- Reference frames
- Homogeneous coordinates
- Kinematics and PostureEngine classes
- Forward kinematics: calculating limb positions from joint angles. (Straightforward matrix multiply.)
- Inverse kinematics: calculating joint angles to achieve desired limb positions. (Hard.)

# Robots As Kinematic Chains

- Tekkotsu allows branching chains, so robots are trees.
- The root of the tree is called the *BaseFrame* in Tekkotsu.
- It is typically at the center of the robot's body.

# Chains = Joints + Links

- A chain is a sequence of joints separated by links.

- We can use transformation matrices to calculate the position of the tip of the chain (joint  $J_2$ ) from the joint angles  $\theta_0$ ,  $\theta_1$  and the link lengths  $L_1$ ,  $L_2$ .
- Each rotational joint has a rotation transform; each link has a translation transform.
- The math for this will be shown later in this lecture.

# AIBO Kinematic Chains

- The AIBO has 9 kinematic chains instead of 6 because branched chains were formerly not supported:
  - 4 for the legs
  - 1 for the head (ending in the camera), 1 for the mouth
  - 3 for the IR range sensors
- All chains begin at the center of the body (base frame).

# Chiara Kinematic Chains

- The Chiara has 8 major kinematic chains:
  - Head / camera / IR
  - Arm
  - Left front leg
  - Right front leg (4-dof)
  - Left middle leg
  - Right middle leg
  - Left back leg
  - Right back leg

# Calliope Kinematic Chains

## BaseFrame

center of axle

WHEEL:L, WHEEL:R

NECK:PAN

NECK:TILT

## CameraFrame

ARM:base

ARM:shoulder

ARM:elbow

ARM:wrist

ARM:wristrot

## GripperFrame

ARM:gripperleft

## LeftFingerFrame

ARM:gripperright

## RightFingerFrame

Use the DisplayKinTree demo to show the kinematic tree of the robot.

Root Control

- > Framework Demos
- > Kinematics Demos
- > DisplayKinTree

# Reference Frames

- Every joint has an associated reference frame.
- Additional reference frames for camera, toes, etc.

- Denavit-Hartenberg conventions: joints rotate about their **z**-axes.
- The **x** and **y** axes follow the *right hand rule*.

# Chain of Reference Frames

- BaseFrame: **z** is up, **x** is forward, **y** is left.
  - This convention is also used for localShS and worldShS.
- Axis of rotation determines **z** for a joint.

- The head chain:

- Base frame      0       $z_0 = \text{"up"}$
- Tilt joint        1       $y_1 = \text{"up"}$
- Pan joint        2
- Nod joint        3
- Camera          4       $z_4 = \text{"out"}$ ,  
 $x_4, y_4 = \text{image plane}$

# Reference Frame Naming Conventions

- Use the same offset-based indexing scheme as for joint names in motion commands and world state vectors:
  - **BaseFrameOffset**
  - HeadOffset+TiltOffset, HeadOffset+PanOffset
  - **CameraFrameOffset**
  - ArmShoulderOffset, ArmElbowOffset, ArmWristOffset, etc.
  - **GripperFrameOffset**
- Denavit-Hartenberg conventions specify how to express the relationship between one reference frame and the next:  $d$ ,  $\theta$ ,  $r$ ,  $\alpha$ .

# Denavit-Hartenberg Video

<http://www.youtube.com/watch?v=rA9tm0gTln8>

# Summary of D-H Conventions

- 1) Move by  $d$  along  $z_{n-1}$
- 2) Rotate by  $\theta$  around  $z_{n-1}$
- 3) Move by  $r$  along  $x_n$ , which is the common normal of  $z_{n-1}$  and  $z_n$
- 4) Rotate by  $\alpha$  along  $x_n$

When  $z_{n-1}$  and  $z_n$  are parallel:

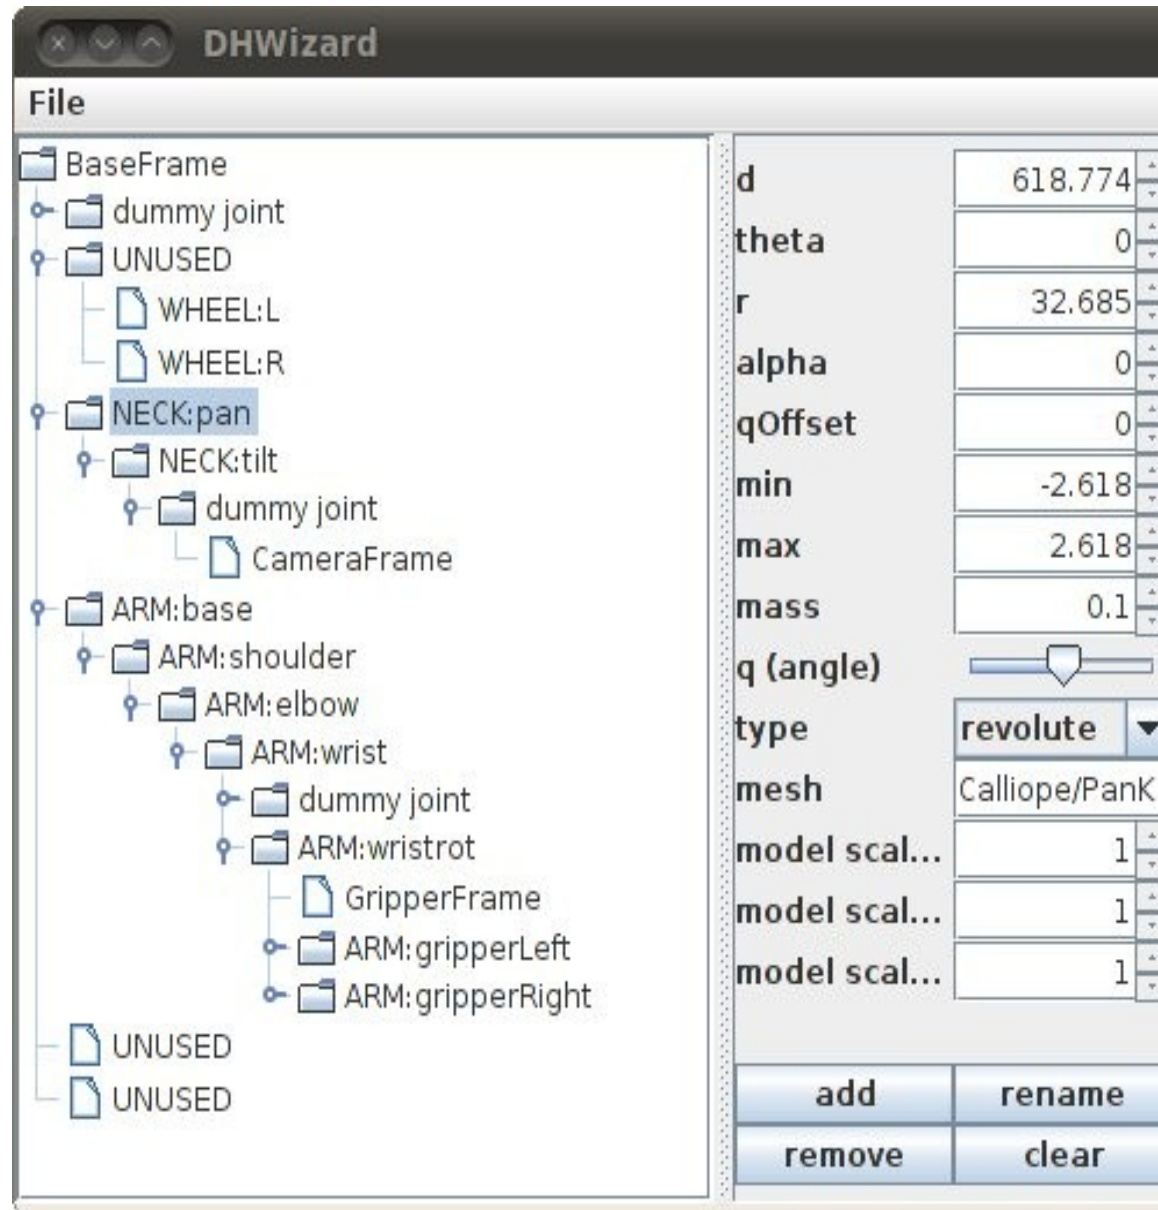

- $d$  is arbitrary
- $\alpha$  is 0

# The Tekkotsu .kin File

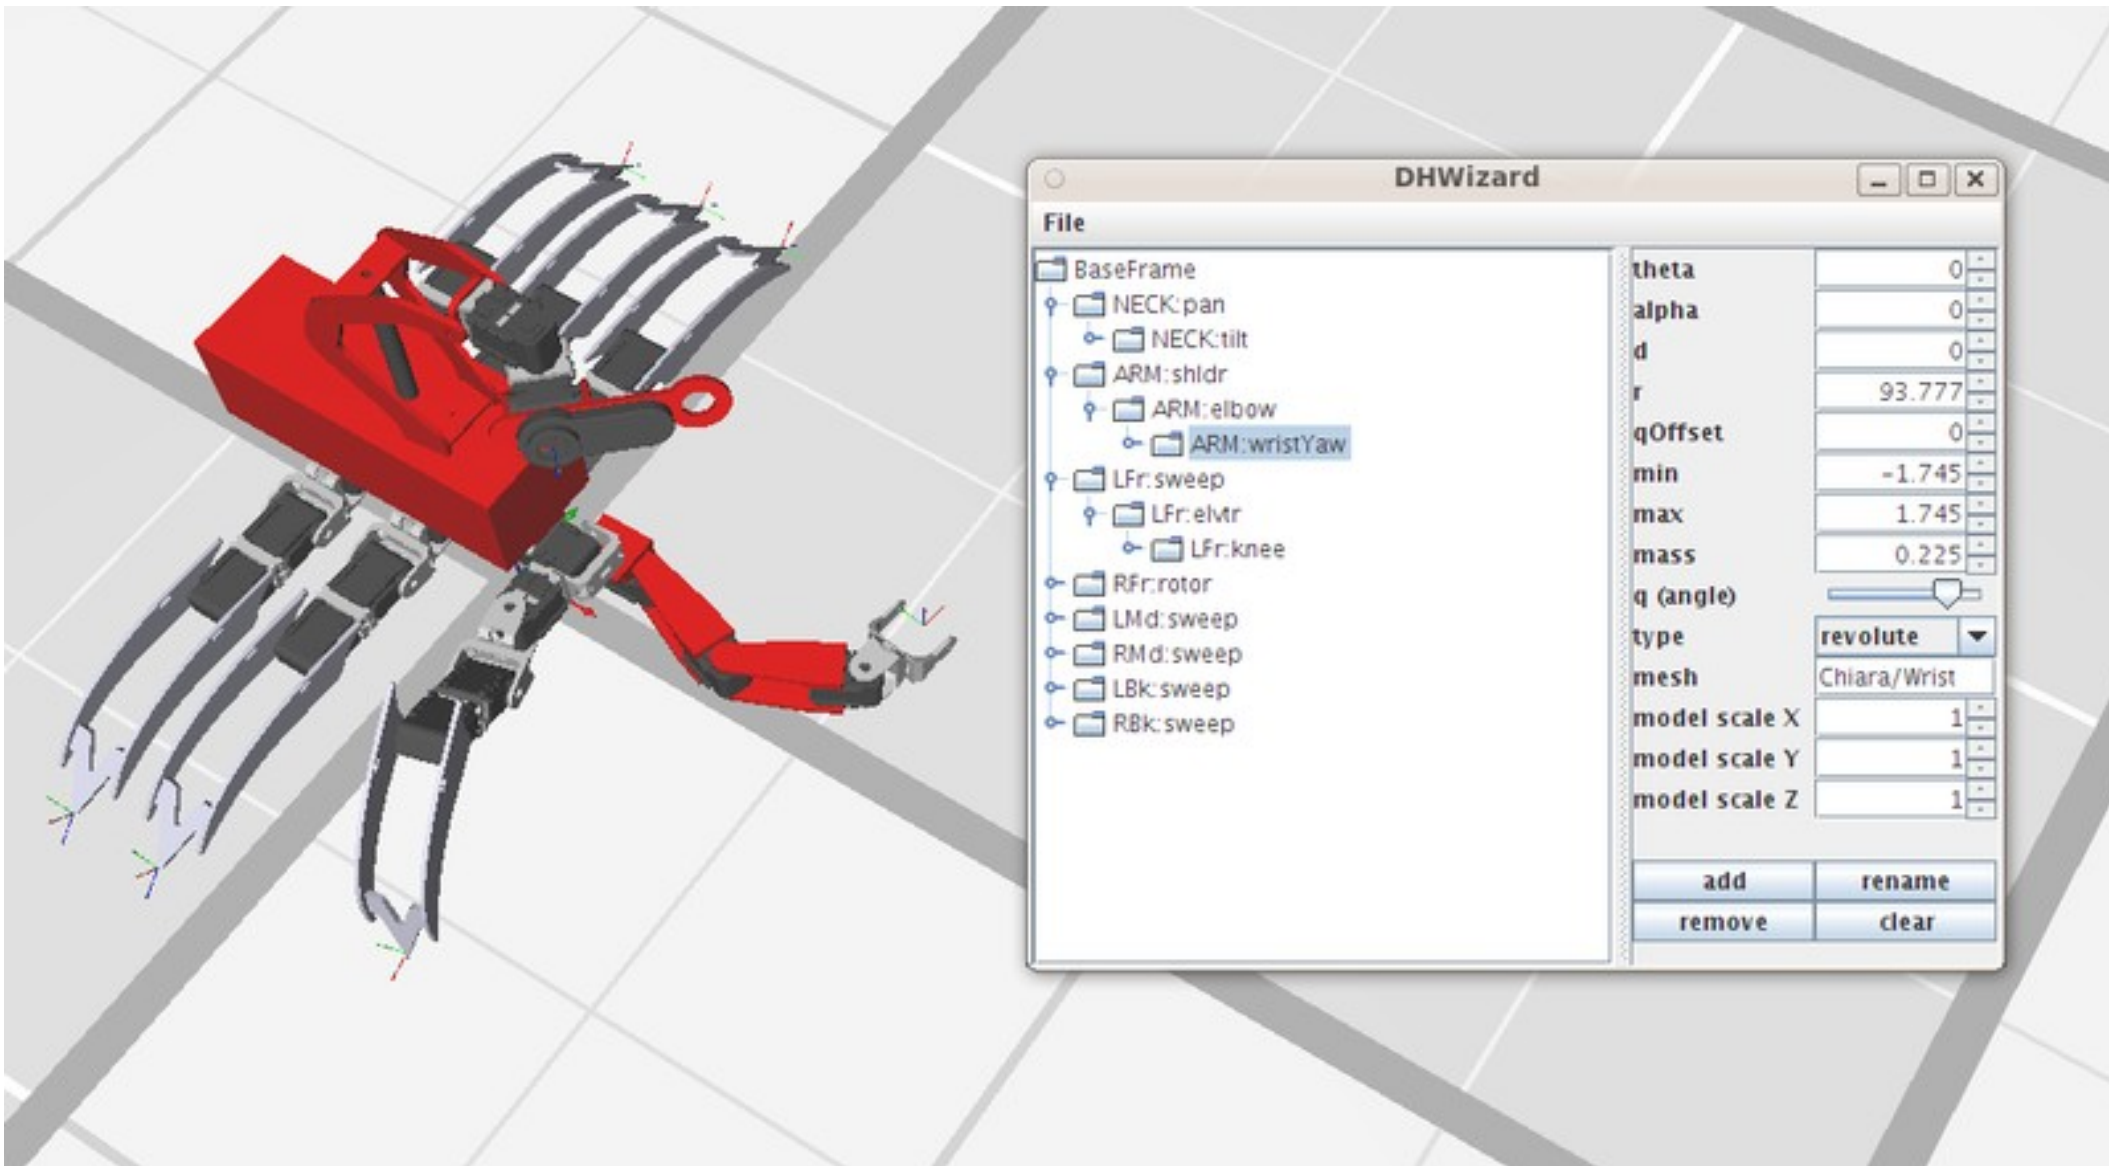

- See `project/ms/config/Calliope5KP.kin`
- Contains four types of information:
  - Kinematic description of the robot following D-H conventions, used by Tekkotsu's kinematics solvers.
  - Additional joint and link information, such as min, max, and offset values, mass, center of mass, etc.
  - Paths to mesh files (models) for selected joints, used by Mirage to render the robot.
  - Collision models for selected components, used by Mirage to determine how the robot interacts with the world.

# DH Wizard

- Tool for editing kinematic descriptions. Outputs a kin file.

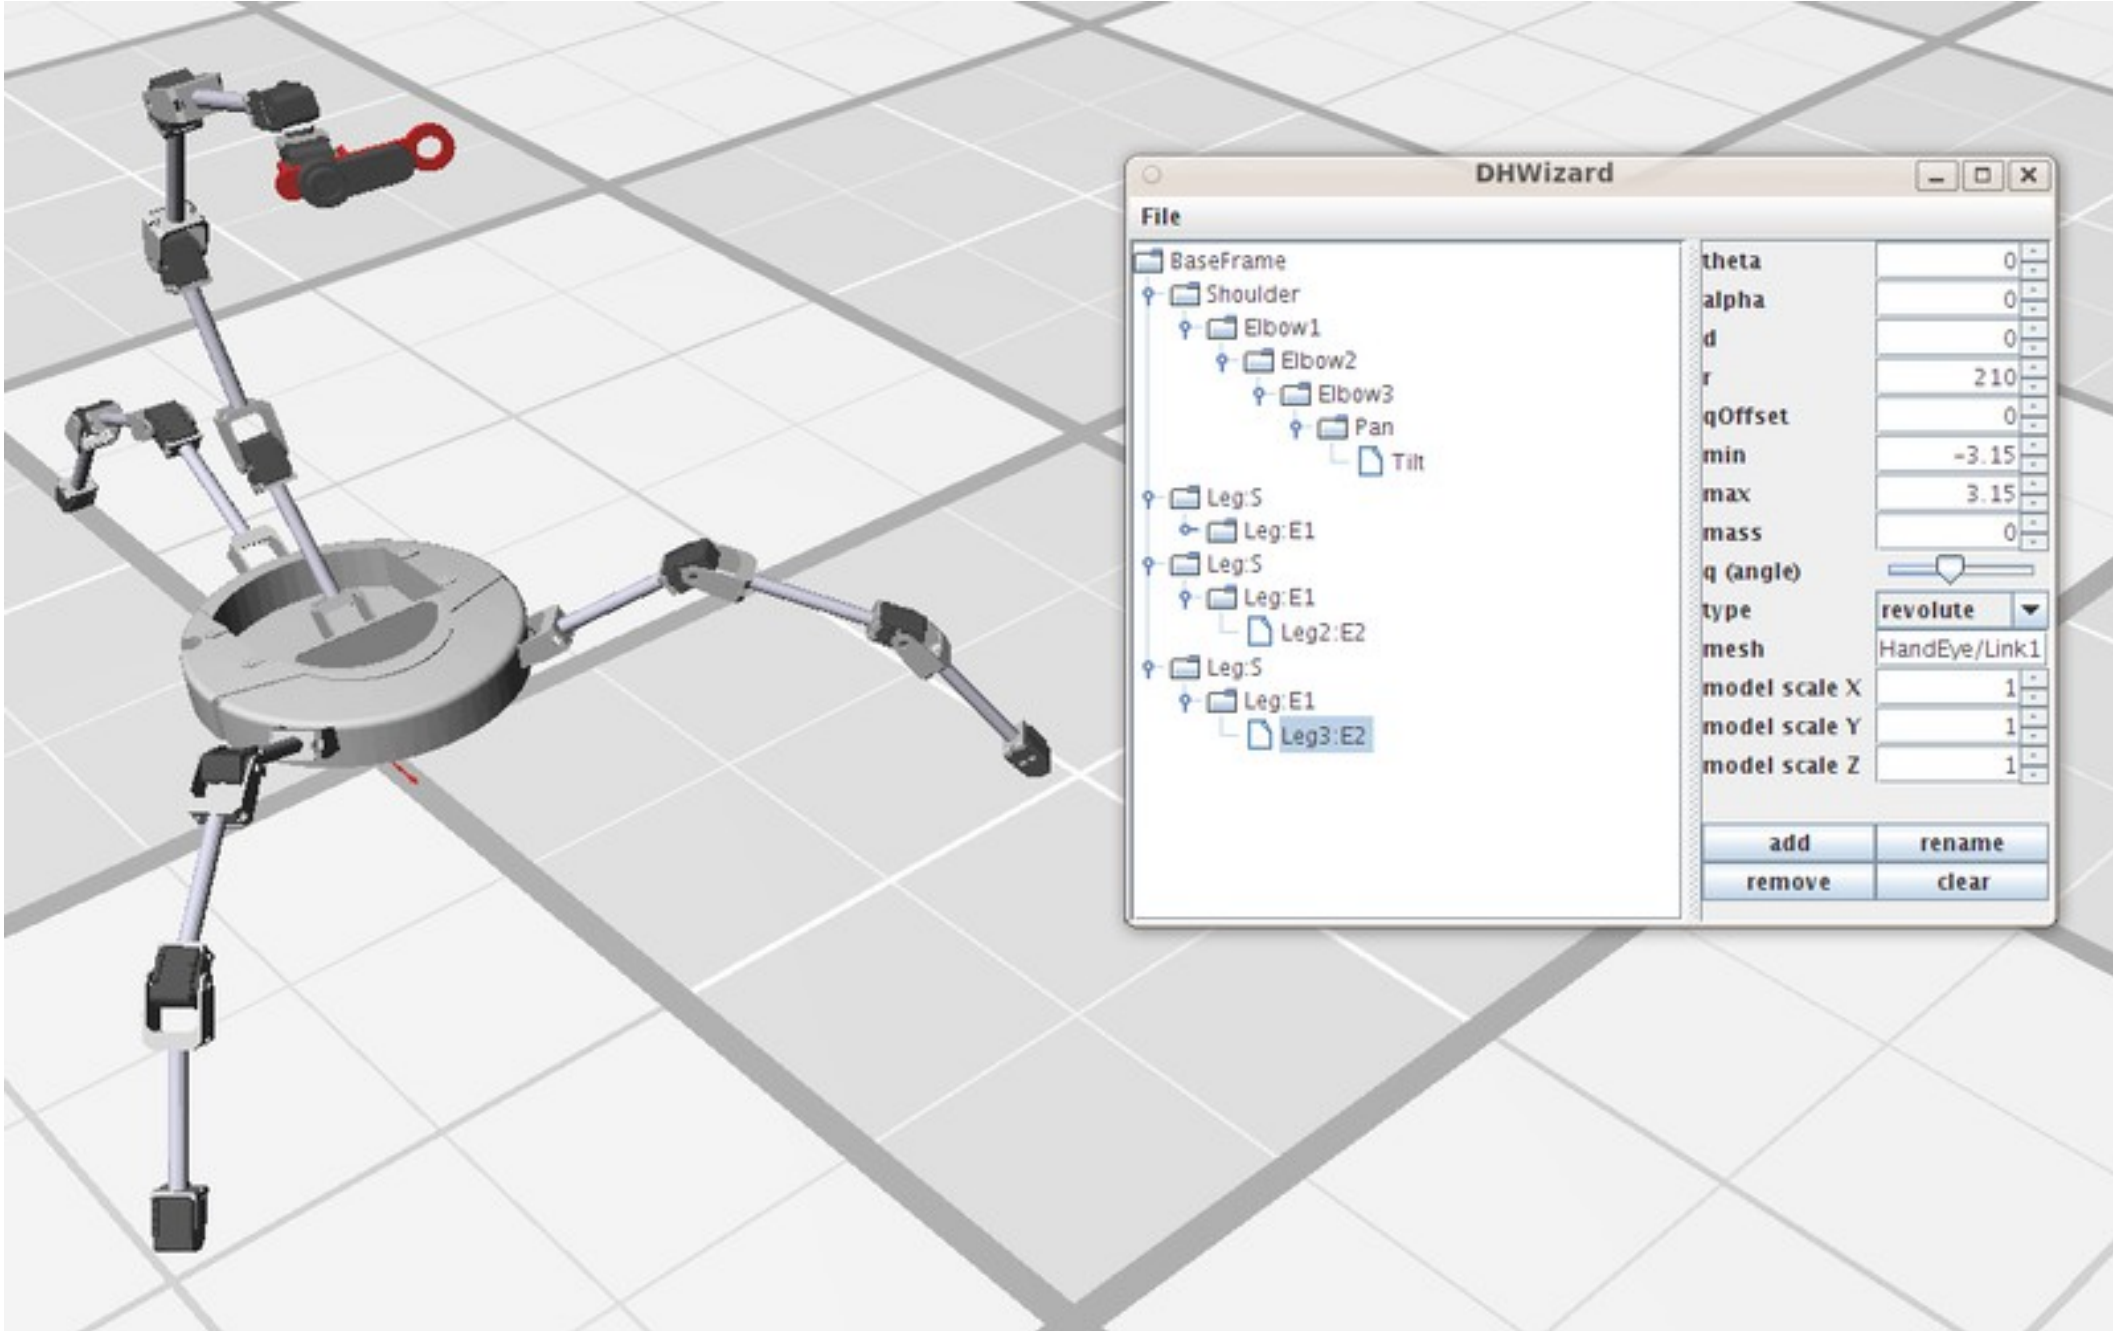

# DH Wizard

# DH Wizard

# Now, The Math...

- How do we represent transformations from one reference frame to the next in a kinematic chain?
  - Homogeneous coordinates
  - Transformation matrices
- How do we perform these calculations in C++?
  - The fmat package
- How do I get Tekkotsu to do the work for me?
  - Forward kinematics solver

# Homogeneous Coordinates

- Represent a point in N-space by an (N+1)-dimensional vector. (Extra component is an inverse scale factor.)
  - In “normal” form, last component is always 1.

$$\vec{v} = \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix}$$

- Exception: points at infinite distance: last component is 0.
- Allows us to perform a variety of transformations using matrix multiplication:

Rotation, Translation, Scaling
- Tekkotsu uses 3D coordinates (so 4-dimensional vectors) for everything.

# Transformation Matrices

- Let  $\theta$  be rotation angle in the x-y plane.  
Let  $dx, dy, dz$  be translation amounts.  
Let  $1/s$  be a scale factor.

$$T = \begin{bmatrix} \cos \theta & \sin \theta & 0 & dx \\ -\sin \theta & \cos \theta & 0 & dy \\ 0 & 0 & 1 & dz \\ 0 & 0 & 0 & s \end{bmatrix}$$

$$T \vec{v} = \begin{bmatrix} x \cos \theta + y \sin \theta + dx \\ -x \sin \theta + y \cos \theta + dy \\ z + dz \\ s \end{bmatrix} = \begin{bmatrix} (x \cos \theta + y \sin \theta + dx)/s \\ (-x \sin \theta + y \cos \theta + dy)/s \\ (z + dz)/s \\ 1 \end{bmatrix}$$

# Transformations Are Composable

- To rotate about point  $p$ , translate  $p$  to the origin, rotate, then translate back.

$$\textit{Translate}(p) = \begin{bmatrix} 1 & 0 & 0 & p.x \\ 0 & 1 & 0 & p.y \\ 0 & 0 & 1 & p.z \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$\textit{Rotate}(\theta) = \begin{bmatrix} \cos \theta & \sin \theta & 0 & 0 \\ -\sin \theta & \cos \theta & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$\textit{RotateAbout}(p, \theta) = \textit{Translate}(p) \cdot \textit{Rotate}(\theta) \cdot \textit{Translate}(-p)$$

# fmat

- Tekkotsu uses the fmat package to represent coordinates and transformation matrices.
- fmat is optimized for efficient representation of small, fixed-size matrices and vectors.

```
fmat::Column<4> v, w;  
v = fmat::pack(5.75, 30.0, 115, 1);  
w = fmat::pack(17, -4.2f, 100, 1);  
  
fmat::Matrix<4,4> T;  
T = v * w.transpose();
```

# fmat::Transform

- Transformation matrices using homogenous coordinates are  $4 \times 4$ .
- But the last row is always  $[0 \ 0 \ 0 \ 1]$ .
- So fmat eliminates the last row and overloads the arithmetic operators to make the math work correctly.
- fmat::Transform is really a `Matrix<3,4>`

# The Kinematics Class

- Tekkotsu contains its own kinematics engine for kinematics calculations, modeled after ROBOOP.
- The Kinematics class provides access to basic functionality for forward kinematics.
- Defined in Tekkotsu/Motion/Kinematics.h
- Global variable **kine** holds a special Kinematics instance:
  - Joint values reference WorldState.
- PostureEngine is a child of Kinematics so it can do kinematics calculations too.

# Converting Between Reference Frames

- Most common conversions are between the base frame (body coordinates) and a limb or camera frame.
- Conversion requires computing a transformation matrix.
- Specify the frame with an unsigned int (a joint offset).

fmat::Transform **linkToBase**(unsigned int link)

fmat::Transform **baseToLink**(unsigned int link)

fmat::Transform **linkToLink**(unsigned int ilink,  
unsigned int olink)

# Reference Frame Conversion 1

- Transform Base to Base:

```
fmat::Transform T = kine->linkToBase(BaseFrameOffset);  
cout << T.fmt("%8.3f") << endl;
```

- Result:

1.000	0.000	0.000	0.000
0.000	1.000	0.000	0.000
0.000	0.000	1.000	0.000
0.000	0.000	0.000	1.000

# Reference Frame Conversion 2

Translate Calliope head pan frame to base frame:

```
const float headpan = state->outputs[HeadOffset+PanOffset];
cout << "Head pan is " << headpan * 180/M_PI
      << " degrees." << endl;

fmat::Transform TpanL = kine->linkToBase(HeadOffset+PanOffset);

cout << "pan linkToBase=\n" << TPanL.fmt("%8.3f") << endl;
```

# At ~Zero Degree Pan Angle

Head pan is 0.0016182 degrees.

```
pan linkToBase=  
[ 1.000  -0.000   0.000  75.230  
  0.000   1.000   0.000   0.000  
  0.000   0.000   1.000 383.916 ]
```

# At ~ 30 Degree Pan Angle

Head pan is 32.7 degrees.

pan linkToBase=

```
[ 0.846 -0.534 0.000 75.230  
  0.534 0.846 -1.000 0.000  
  0.000 0.000 0.000 383.916 ]
```

$\cos(30^\circ) = 0.866$
$\sin(30^\circ) = 0.500$

# How About Tilt w/Head Centered?

Head pan is -0.001547 degrees.

pan linkToBase=

```
[ 1.000 -0.000 0.000 75.230
  0.000 1.000 0.000 0.000
  0.000 0.000 1.000 383.916 ]
```

Head tilt is 0.009223 degrees.

tilt linkToBase=

```
[ 1.000 -0.000 -0.000 97.730
 -0.000 -0.000 1.000 -0.001
 0.000 1.000 -0.000 422.916 ]
```

# Forward Kinematics: Measure Distance From Wrist to Arm Base

```
$nodeclass ComputeDistance : StateNode : doStart {  
  
    fmat::Transform wrist =  
        kine->linkToBase(ArmWristOffset);  
    fmat::Column<3> wristPos = wrist.translation();  
  
    fmat::Transform armbase =  
        kine->linkToBase(ArmBaseOffset);  
    fmat::Column<3> armbasePos = armbase.translation();  
  
    float dist = (wristPos-armbasePos).norm();  
  
    cout << "Distance is " << setw(5) < dist << " mm." << endl;  
  
}
```

```
startnode: ComputeDistance =T(1000)=> startnode
```

# Inverse Kinematics

- Inverse kinematics finds the joint angles to put an effector at a particular point in space.
- Hard problem:
  - solution space can be discontinuous
  - can be highly nonlinear
  - multiple solutions may be possible
  - maybe no solution (so find closest approximation)
- Example: `lookAtPoint(x,y,z)`
  - point described in base frame coordinates
  - calculates head joint angles

# CameraTrackGripper Demo

Root Control > Framework Demos > Kinematics Demos > CameraTrackGripper

```
$nodeclass CameraTrackGripper : StateNode : {  
  
    $nodeclass HeadMover : HeadPointerNode : doStart {  
        fmat::Transform Tgripper =  
            kine->linkToBase(GripperFrameOffset);  
  
        fmat::Column<3> Pgripper = Tgripper.translation();  
  
        std::cout << "Transform:\n"  
                    << Tgripper.fmt("%8.3f") << std::endl;  
  
        getMC()->lookAtPoint(Pgripper[0], Pgripper[1], Pgripper[2]);  
    }  
}
```

# CameraTrackGripper (2)

```
virtual void setup() {
  MotionManager::MC_ID headmc =
    addMotion(MotionPtr<HeadPointerMC>());

  $statemachine{

    startnode: StateNode =N=> {headmover, unrelaxed}

    headmover: HeadMover[setMC(headmc)] ← Initializer
      =E(sensorEGID)=> headmover expression

    unrelaxed: SpeechNode("arm not relaxed")
      =B(GreenButOffset)=> armrelaxer

    armrelaxer: SpeechNode("arm is relaxed")
      =N=> PIDNode(ArmOffset, ArmOffset+NumArmJoints, 0.f)
      =B(GreenButOffset)=> unrelaxed
  }
}
```

# Solving the 1-Link Arm

Reachable if:  $L_1 = \sqrt{x^2 + y^2}$

Solution:  $\theta_1 = \text{atan2}(y, x)$

# Configuration Space vs. Work Space

Consider a 2-link arm, with joint constraints

$$0^\circ < \theta_0 < 90^\circ, \quad -90^\circ < \theta_1 < 90^\circ$$

*Configuration Space: robot's internal state space (e.g. joint angles)*

*Work Space: set of all possible end-effector positions*

# Solving the 2-Link Planar Arm

$$c_2 = \frac{x^2 + y^2 - L_1^2 - L_2^2}{2L_1L_2}$$

$$s_2^+ = \sqrt{1 - c_2^2}$$

$$\theta_2^+ = \text{atan2}(s_2^+, c_2)$$

$$K_1 = L_1 + c_2 L_2$$

$$K_2 = s_2^+ L_2$$

$$\theta_1 = \text{atan2}(y, x) - \text{atan2}(K_2, K_1)$$

Reachable if:  $c_2^2 \leq 1$

# Two Possible Solutions

$$s_2^- = -\sqrt{1-c_2^2}$$
$$\theta_2^- = \text{atan2}(s_2^-, c_2)$$

**“Elbow up”**

$$s_2^+ = \sqrt{1-c_2^2}$$
$$\theta_2^+ = \text{atan2}(s_2^+, c_2)$$

**“Elbow down”**

# How Many Degrees of Freedom Are Enough?

- With 2 dof you can put the end effector at any point in the workspace.
- But you can't control end-effector orientation.
  - What if the arm is holding a screwdriver?
- With 3 dof in the same plane you can control both position and orientation.

# Solving the 3-Link Planar Arm

- Choose tool angle  $\phi$
- Given target position  $x_t, y_t$ , calculate wrist position:  $x_w$  and  $y_w$
- Solve 2-link problem to put wrist at  $x_w, y_w$ .

If you don't know  $\phi$ , pick an arbitrary value and search from there until you find a solution that works.

# Towers of Hanoi in the Plane

Video by Michel Brudzinski and Evan Patton at RPI.

# Customized Kinematics Solvers

- For some simple kinematic chains, such as a pan/tilt, we can write analytical solutions to the IK problem.
- For the general case, must use gradient descent search.

See IK videos.

# Inverse Kinematics Functions

- Inverse kinematics solver included in PostureEngine:  
  
`solveLinkPosition(const fmat::Column<3> &Ptgt,  
 unsigned int link,  
 const fmat::Column<3> &Peff)`
  - Ptgt is the target point to move to (in base frame coordinates)
  - link is the index of some effector on the body, e.g., GripperFrameOffset
  - Peff is a point on the effector that is to be moved to Ptgt, in the reference fame of that effector.
- Returns true if a solution was found. False if no solution exists (e.g., joint limits exceeded, distance too far, etc.)
- Solution is stored in the PostureEngine as joint values.

# GripperTrackCamera

```
$nodeclass GripperTrackCamera : StateNode {  
  
    $nodeclass ArmMover : PostureNode : doStart {  
        fmat::Column<3> targetInCam = fmat::pack(0, 0, 100);  
        fmat::Column<3> targetInBase =  
            kine->linkToBase(CameraFrameOffset) * targetInCam;  
        fmat::Column<3> noOffset = fmat::pack(0, 0, 0);  
  
        getMC()->solveLinkPosition(targetInBase,  
                                   LeftFingerFrameOffset,  
                                   noOffset);  
    }  
}
```

# GripperTrackCamera (2)

```
virtual void setup() {  
    MotionManager::MC_ID armmc =  
        addMotion(MotionPtr<PostureMC>());  
  
    $statemachine{  
        startnode: ArmMover[setMC(armmc)]  
            =E(sensorEGID)=> startnode  
    }  
}
```

# Additional IK Functions

PostureEngine provides:

- `solveLinkPosition(...)`
- `solveLinkVector(...)`
- `solveLinkOrientation(...)`
- `solveLink(...)`

The actual IK calculations for Calliope are done in  
`Tekkotsu/Motion/IKCalliope.cc`

# Calliope's 5-dof ARM

- Only one degree of freedom in the horizontal plane:
  - ARM:base
- Three degrees of freedom in a vertical plane:
  - ARM:shoulder, ARM:elbow, ARM:wrist
- An additional degree of freedom in an orthogonal plane:
  - ARM:wristrot
- Conclusion: can only partially control the 3D pose of the end-effector.
  - **What kinds of motions can this arm not make?**
