Time Measurement

October 25, 2001

Topics

- Time scales
- Interval counting
- Cycle counters
- K-best measurement scheme

Computer Time Scales

Two Fundamental Time Scales

- Processor: $\sim 10^{-9}$ seconds
 - External events: $\sim 10^{-2}$ seconds
 - Keyboard input
 - Disk seek
 - Screen refresh
- Can execute many instructions while waiting for external event to occur
 - Can alternate among processes without anyone noticing

Implication

Measurement Challenge

How Much Time Does Program X Require?

- CPU time
 - How many total seconds are used when executing X?
 - Measure used for most applications
 - Small dependence on other system activities
 - Actual (“Wall”) Time
 - How many seconds elapse between the start and the completion of X?
 - Depends on system load, I/O times, etc.
- ## Confounding Factors
- How does time get measured?
 - Many processes share computing resources
 - Transient effects when switching from one process to another
 - Suddenly, the effects of alternating among processes become noticeable

“Time” on a Computer System

= **user time** (*time executing instructions in the user process*)

= **system time** (*time executing instructions in kernel on behalf of user process*)

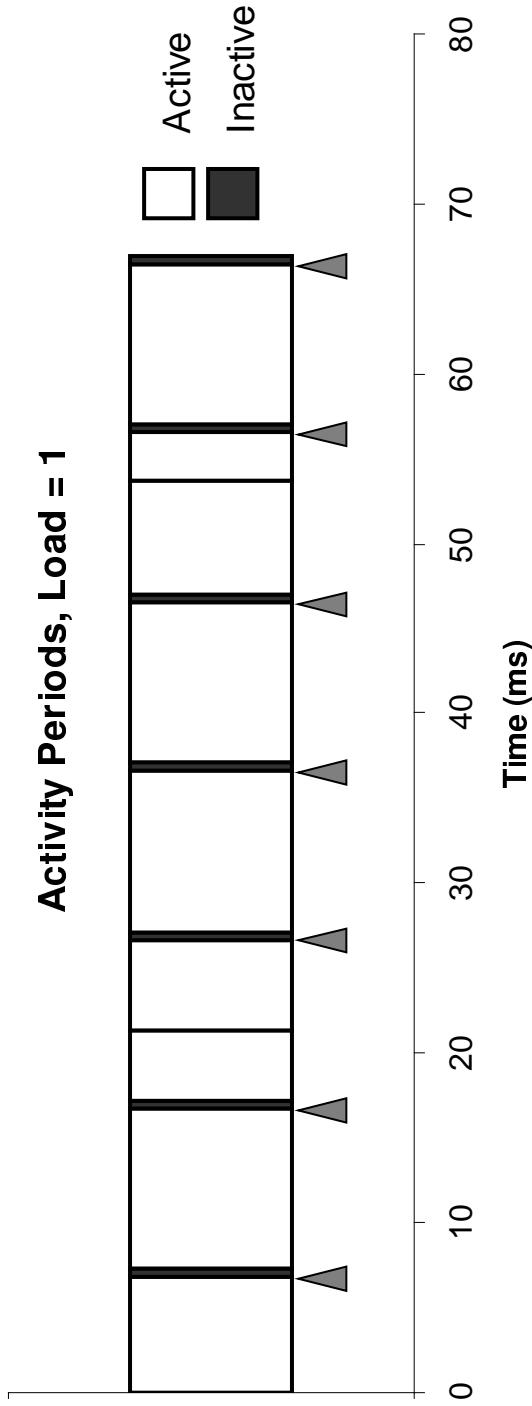

= **some other user's time** (*time executing instructions in different user's process*)

+ + = **real (wall clock) time**

We will use the word “time” to refer to user time.

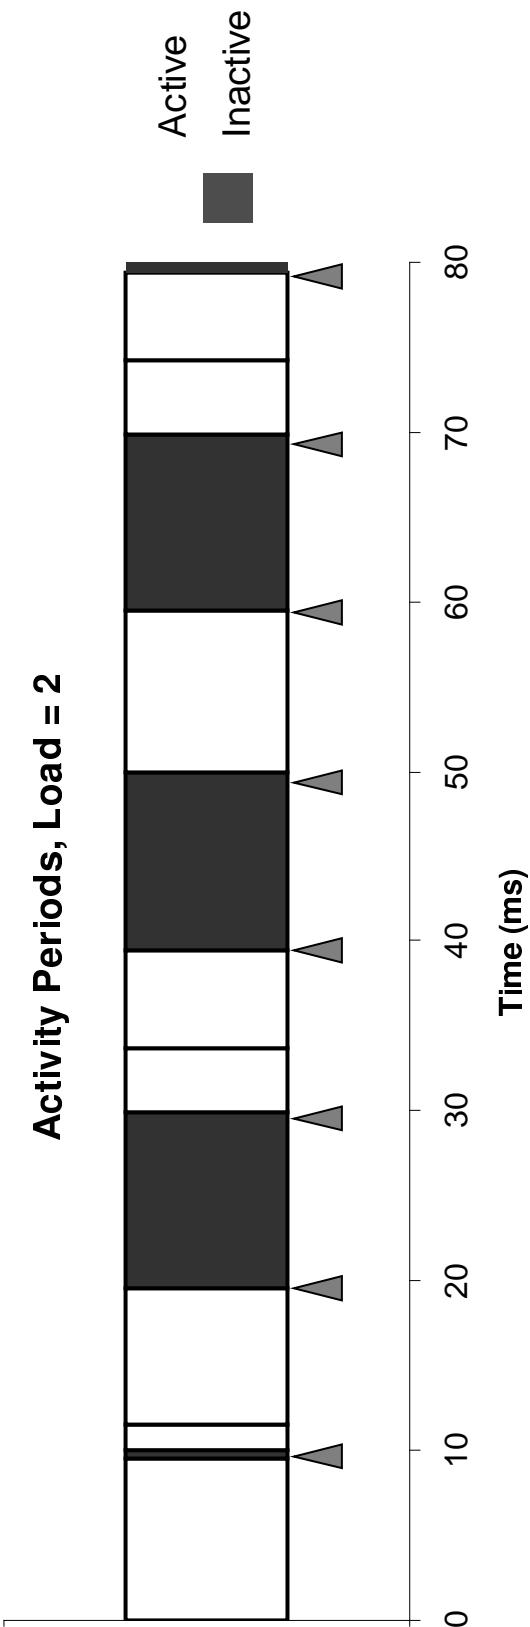

Activity Periods: Light Load

- **Most of the time spent executing one process**
- **Periodic interrupts every 10ms**
 - Interval timer
 - Keep system from executing one process to exclusion of others
- **Other interrupts**
 - Due to I/O activity
- **Inactivity periods**
 - System time spent processing interrupts
 - ~250,000 clock cycles

Activity Periods: Heavy Load

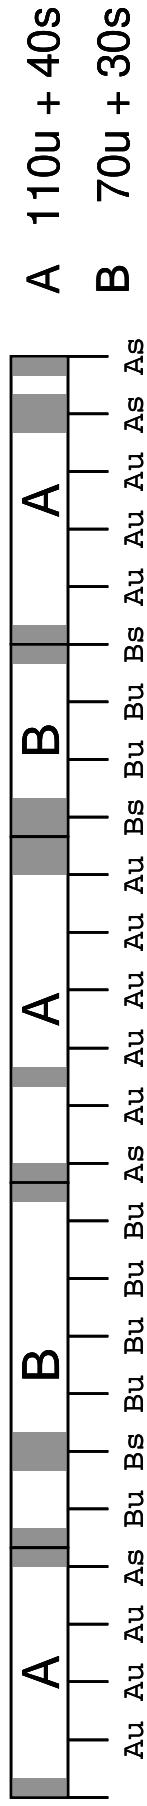

- **Sharing processor with one other active process**
- **Periodic interrupts every 10ms**
 - Interval timer
 - Keep system from executing one process to exclusion of others
- **Other interrupts**
 - Due to I/O activity
- **Inactivity periods**
 - System time spent processing interrupts
 - Periods when other process executes

Interval Counting

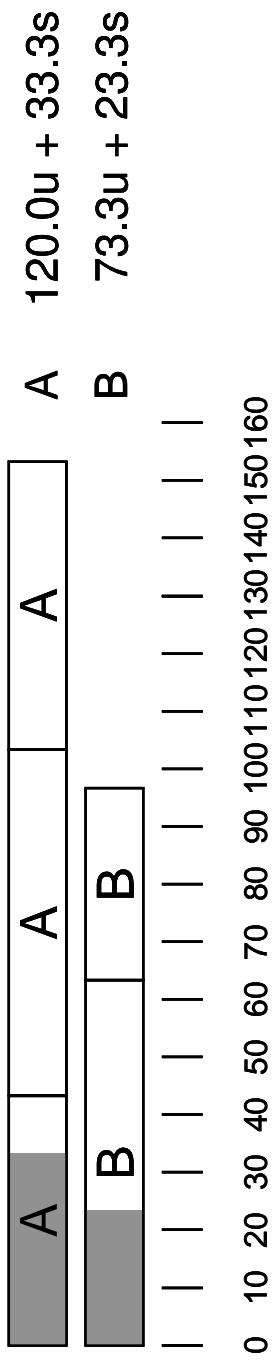

OS Measures Runtimes Using Interval Timer

- Each time get timer interrupt, increment timer for executing process
 - User time if running in user mode
 - System time if running in kernel mode

(a) Interval Timings

(b) Actual Times

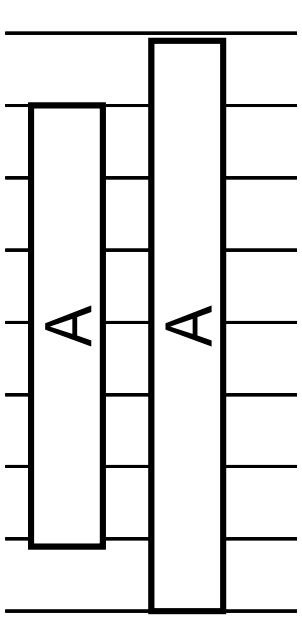

Unix time Command

```
time make osevent
gcc -O2 -Wall -g -march=i486 -c clock.c
gcc -O2 -Wall -g -march=i486 -c options.c
gcc -O2 -Wall -g -march=i486 -c load.c
gcc -O2 -Wall -g -march=i486 -o osevent osevent.c .
0.820u 0.300s 0:01.32 84.8%
0+0k 0+0io 4049pf+0w
```

- **0.82 seconds user time**
 - 82 timer intervals
- **0.30 seconds system time**
 - 30 timer intervals
- **1.32 seconds wall time**
- **84.8% of total was used running these processes**
 - $(.82 + 0.3) / 1.32 = .848$

Accuracy of Interval Counting

0 10 20 30 40 50 60 70 80

Worst Case Analysis

- Timer Interval = δ
- Single process segment measurement can be off by $\pm\delta$
- No bound on error for multiple segments
 - Could consistently underestimate, or consistently overestimate

Average Case Analysis

- Over/underestimates tend to balance out
- As long as total run time is sufficiently large
 - > 1 second
- Consistently miss 4% overhead due to timer interrupts

Cycle Counters

- **Most modern systems have built in registers that are incremented every clock cycle**
 - Very fine grained
 - Maintained as part of process state
 - » In Linux, counts elapsed global time
- **Special assembly code instruction to access**
- **On (recent model) Intel machines:**
 - 64 bit counter.
 - RDTSC instruction sets %edx to high order 32-bits, %eax to low order 32-bits

Wrap Around Times for 550 MHz machine

- Low order 32-bits wrap around every $2^{32} / (550 * 10^6) = 7.8 \text{ seconds}$
- High order 64-bits wrap around every $2^{64} / (550 * 10^6) = 33539534679 \text{ seconds}$
- 1065.3 years

Measuring with Cycle Counter

Idea

- Get current value of cycle counter
 - Store as pair of unsigned's cyc_hi and cyc_lo
- Compute something
- Get new value of cycle counter
- Perform double precision subtraction to get elapsed cycles

```
/* Keep track of most recent reading of cycle counter */
static unsigned cyc_hi = 0;
static unsigned cyc_lo = 0;

void start_counter()
{
    /* Get current value of cycle counter */
    access_counter(&cyc_hi, &cyc_lo);
}
```

Accessing the Cycle Counter (cont.)

- GCC allows inline assembly code with mechanism for matching registers with program variables
- Code only works on x86 machine compiling with GCC

```
void access_counter(unsigned *hi, unsigned *lo)
{
    /* Get cycle counter */
    asm("rdtsc; movl %%edx, %0; movl %%eax, %1"
        : "=r" (*hi), "=r" (*lo)
        : /* No input */
        : "%edx", "%eax");
}
```

- Emit assembly with rdtsc and two movl instructions
- Code generates two outputs:
 - Symbolic register %0 should be used for *hi
 - Symbolic register %1 should be used for *lo
- Code has no inputs
- Registers %eax and %edx will be overwritten

Completing Measurement

- Get new value of cycle counter
- Perform **double precision subtraction** to get elapsed cycles
- Express as double to avoid overflow problems

```
double get_counter()
{
    unsigned ncyc_hi, ncyc_lo
    unsigned hi, lo, borrow;
    /* Get cycle counter */
    access_counter(&ncyc_hi, &ncyc_lo);
    /* Do double precision subtraction */
    lo = ncyc_lo - cyc_lo;
    borrow = lo > ncyc_lo;
    hi = ncyc_hi - cyc_hi - borrow;
    return (double) hi * (1 << 30) * 4 + lo;
}
```

Timing With Cycle Counter

Determine Clock Rate of Processor

- Count number of cycles required for some fixed number of seconds

```
double MHZ;  
int sleep_time = 10;  
start_counter();  
sleep(sleep_time);  
MHZ = get_counter() / (sleep_time * 1e6);
```

Time Function P

- First attempt: Simply count cycles for one execution of P

```
double tsecs;  
start_counter();  
P();  
tsecs = get_counter() / (MHz * 1e6);
```

Timing with Cycle Counter

```
double MHZ;  
int sleep_time = 10;  
start_counter();  
sleep(sleep_time);  
MHZ = get_counter() / (sleep_time * 1e6);
```

```
double tsecs;  
start_counter();  
P();  
tsecs = get_counter() / (MHZ * 1e6);
```

Measurement Pitfalls

Overhead

- Calling `get_counter()` incurs small amount of overhead
- Want to measure long enough code sequence to compensate

Unexpected Cache Effects

- artificial hits or misses
- e.g., these measurements were taken with the *Alpha* cycle counter:

```
foo1 (array1, array2, array3);      /* 68,829 cycles */  
foo2 (array1, array2, array3);      /* 23,337 cycles */
```

vs.

```
foo2 (array1, array2, array3);      /* 70,513 cycles */  
foo1 (array1, array2, array3);      /* 23,203 cycles */
```

Dealing with Overhead & Cache Effects

- Always execute function once to “warm up” cache
- Keep doubling number of times execute P() until reach some threshold
 - Used CMIN = 500000

```
int cnt = 1;
double cmeas = 0;
double cycles;
do {
    int c = cnt;
    P();
    get_counter();
    /* Warm up cache */
    while (c-- > 0)
        P();
    cmeas = get_counter();
    cycles = cmeas / cnt;
    cnt += cnt;
} while (cmeas < CMIN); /* Make sure have enough */
return cycles / (1e6 * MHZ);
```

Multitasking Effects

Cycle Counter Measures Elapsed Time

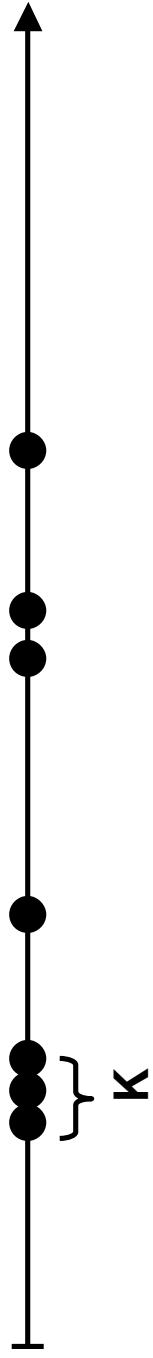

- Keeps accumulating during periods of inactivity
 - System activity
 - Running other processes

Key Observation

- Cycle counter never underestimates program run time
- Possibly overestimates by large amount

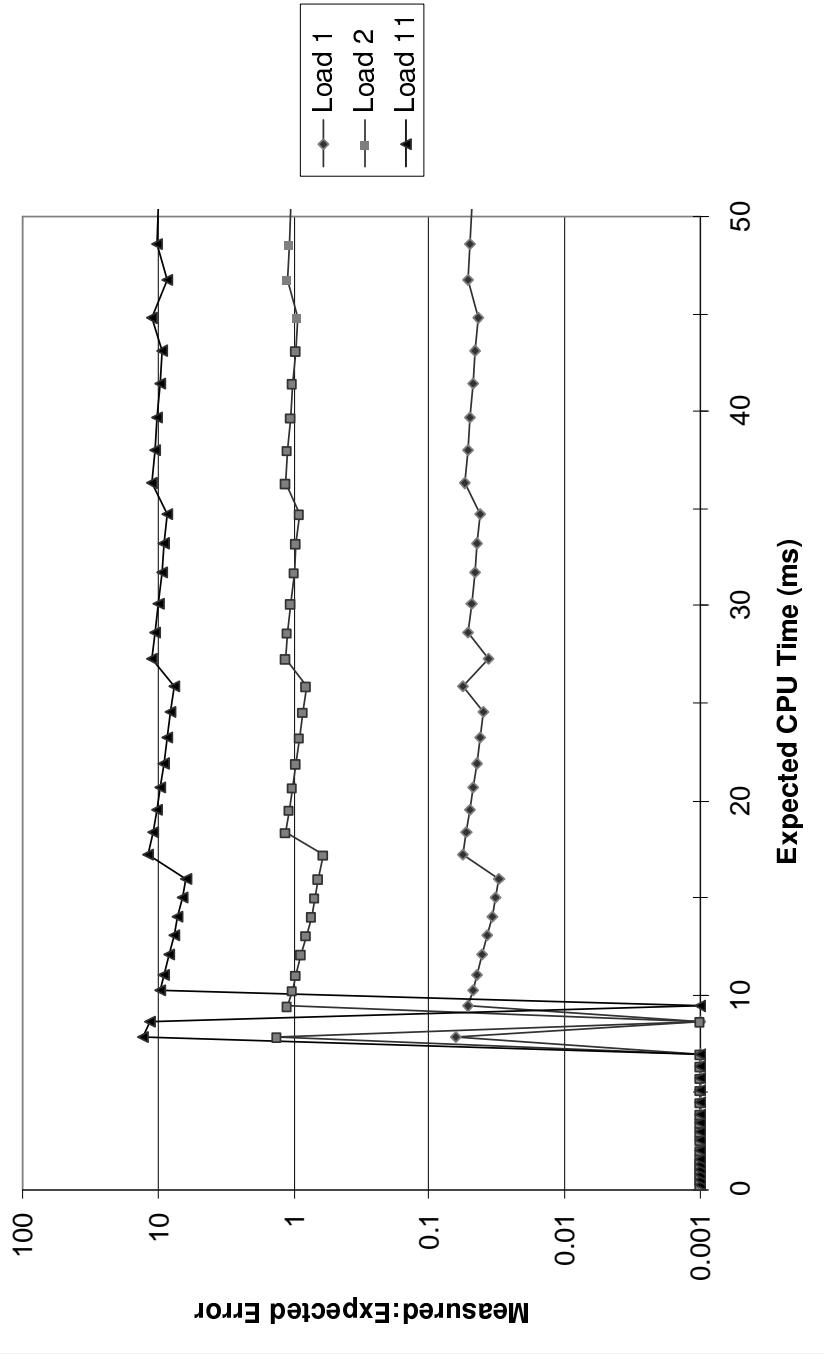

K-Best Measurement Scheme

- Perform up to N (e.g., 20) measurements of function
- See if fastest K (e.g., 3) within some relative factor ε (e.g., 0.001)

K-Best Validation

Intel Pentium III, Linux

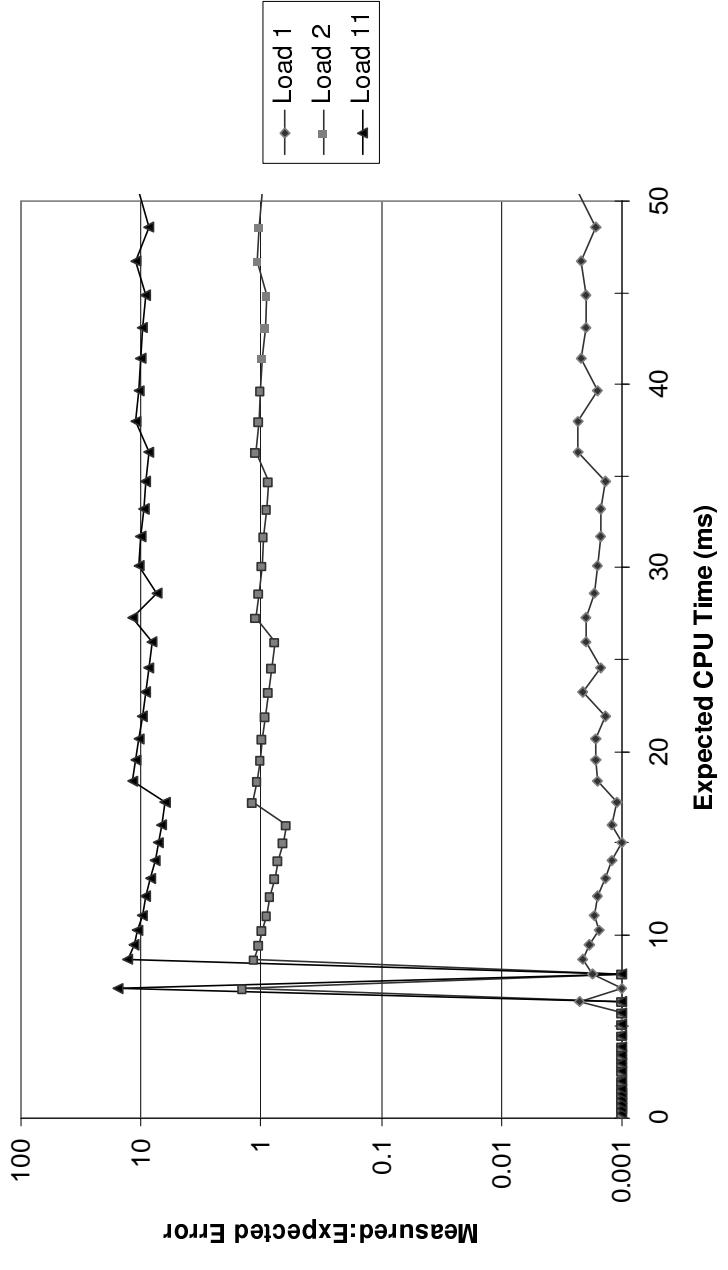

- **Very good accuracy for < 8ms**
- **Less accurate of > 10ms**
- **Within one timer interval**
- **Even when heavily loaded**

- **Light load: ~4% error**
 - Interval clock interrupt handling
- **Heavy load: Very high error**

Compensate For Timer Overhead

$$K = 3, \varepsilon = 0.001$$

Intel Pentium III, Linux
Compensate for Timer Interrupt Handling

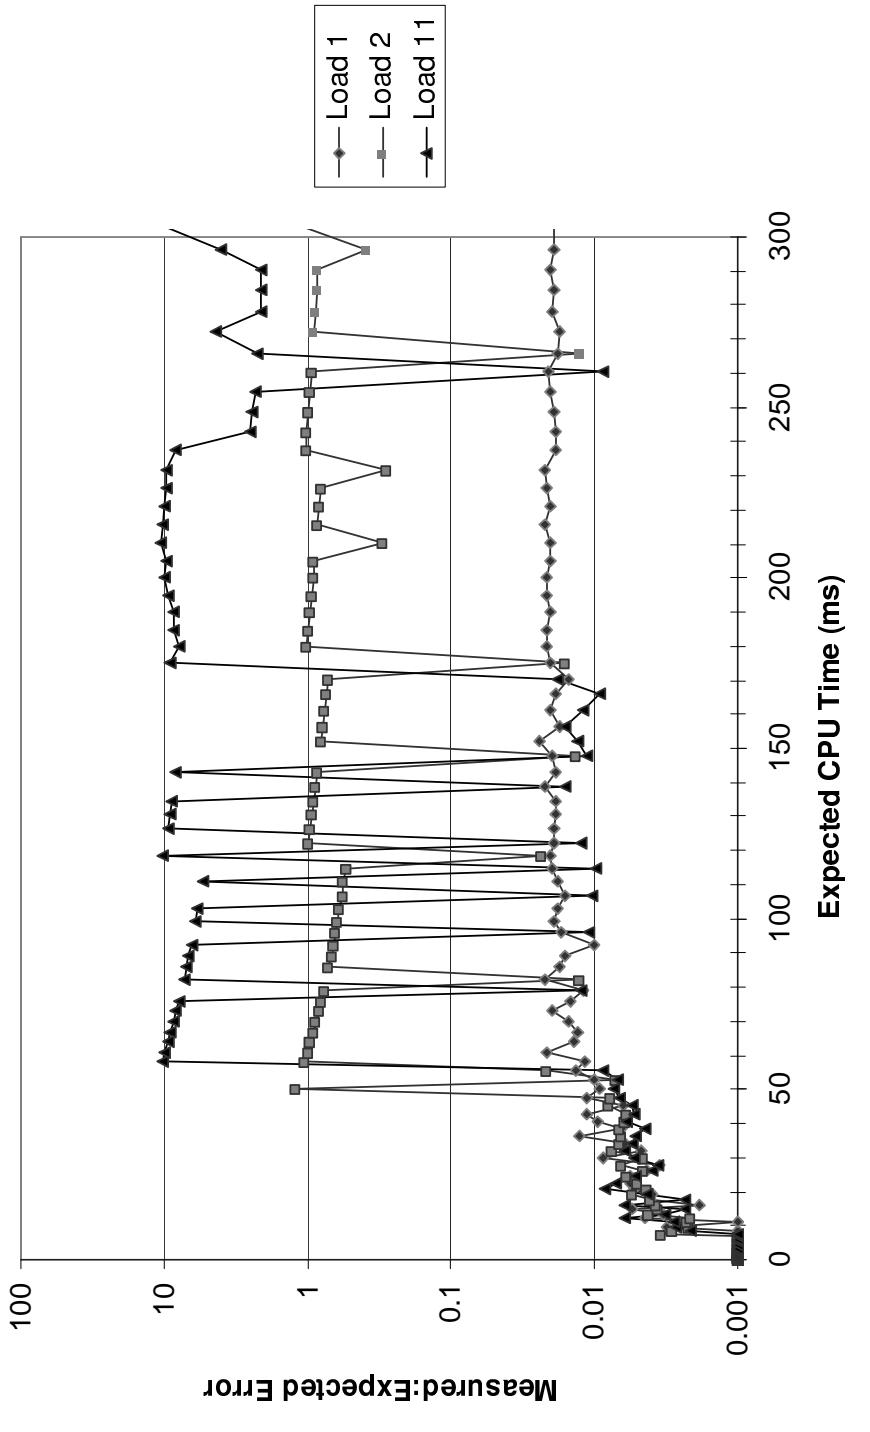

Subtract Timer Overhead

- Estimate overhead of single interrupt by measuring periods of inactivity
- Call interval timer to determine number of interrupts that have occurred

K-Best on NT

$$K = 3, \varepsilon = 0.001$$

Acceptable accuracy for < 50ms

- Scheduler allows process to run multiple intervals
- Light load: 2% error
- Heavy load: Generally very high error

Less accurate of > 10ms

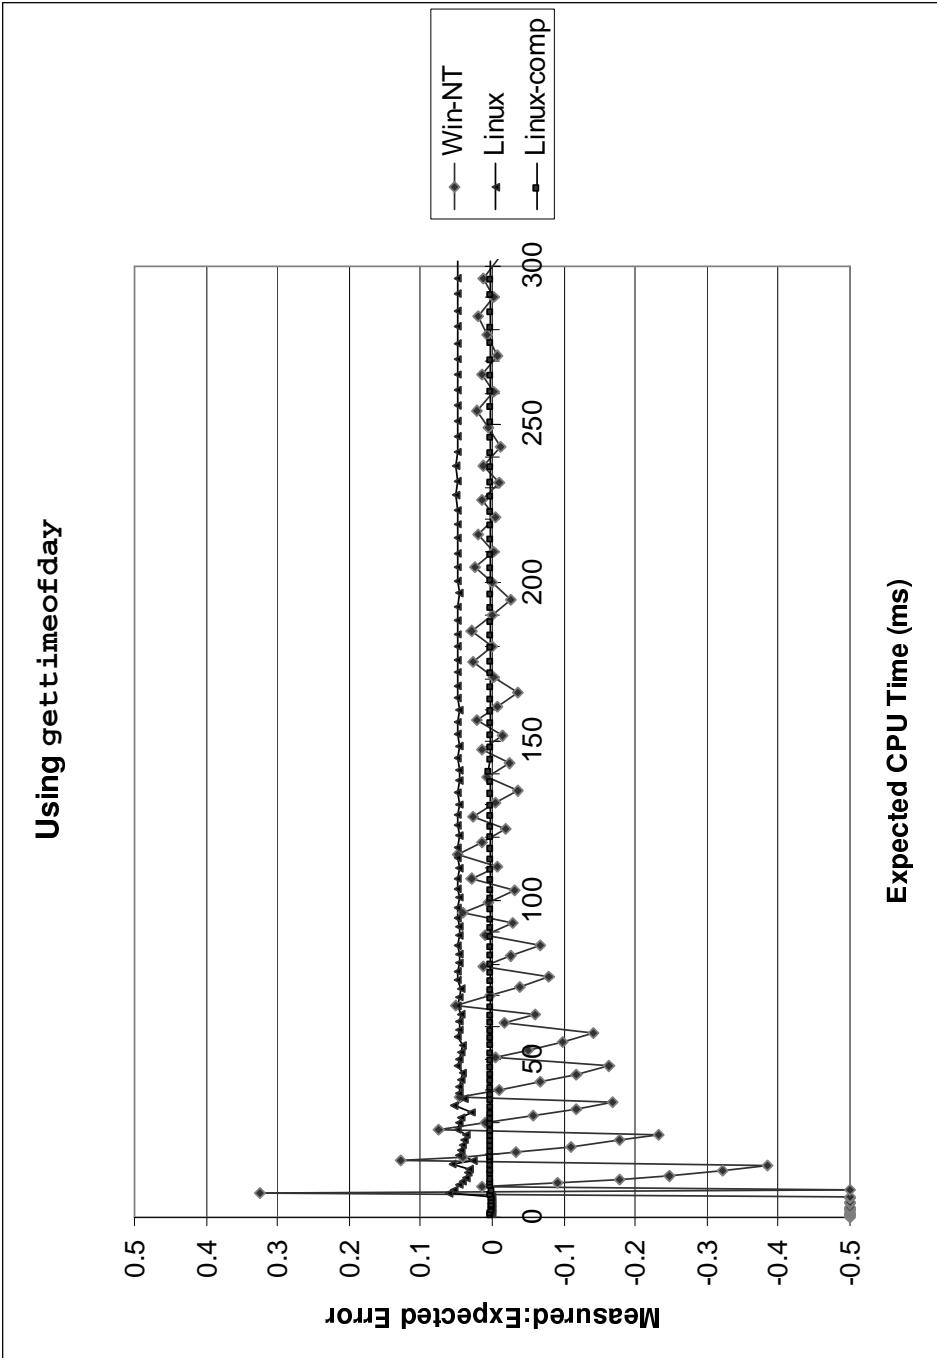

Time of Day Clock

- Unix `gettimeofday()` function
- Return elapsed time since reference time (Jan 1, 1970)
- Implementation
 - Uses interval counting on some machines
 - » Coarse grained
 - Uses cycle counter on others
 - » Fine grained, but significant overhead and only 1 microsecond resolution

```
#include <sys/time.h>
#include <unistd.h>

struct timeval tstart, tfinish;
double tsecs;
gettimeofday(&tstart, NULL);
P();
gettimeofday(&tfinish, NULL);
tsecs = (tfinish.tv_sec - tstart.tv_sec) +
1e6 * (tfinish.tv_usec - tstart.tv_usec);
```

K-Best Using gettimeofday

Linux

- As good as using cycle counter
- For times > 10 microseconds

class18.ppt

Windows

- Implemented by interval counting
- Too coarse-grained

Measurement Summary

Timing is highly case and system dependent

- What is overall duration being measured?

- > 1 second: interval counting is OK

- << 1 second: must use cycle counters

- On what hardware / OS / OS version?

- Accessing counters

- » How gettimeofday is implemented

- Timer interrupt overhead

- Scheduling policy

Devising a Measurement Method

- Long durations: use Unix timing functions

- Short durations

- If possible, use gettimeofday

- Otherwise must work with cycle counters

- K-best scheme most successful
