

# Binary Decision Diagrams and Symbolic Model Checking

Randy Bryant	CMU
Ed Clarke	CMU
Ken McMillan	Cadence
Allen Emerson	U Texas

<http://www.cs.cmu.edu/~bryant>

## Binary Decision Diagrams

### Restricted Form of Branching Program

- Graph representation of Boolean function
- Canonical form
- Simple algorithms to construct & manipulate

### Application Niche

- Problems expressed as Quantified Boolean Formulas
- A lot of interesting problems are in PSPACE

### Symbolic Model Checking

- Prove properties about large-scale, finite-state system
- Successfully used to verify hardware systems

## Boolean Function as Language

Truth Table

$x_1$	$x_2$	$x_3$	$f$
0	0	0	0
0	0	1	0
0	1	0	0
0	1	1	1
1	0	0	0
1	0	1	1
1	1	0	0
1	1	1	1

Language

{ 011,  
101,  
111 }

DFA

- View  $n$ -variable Boolean function as language  $\subseteq \{0,1\}^n$
- Reduced DFA is canonical representation

- 3 -

## From DFA to OBDD

### Canonical representation of Boolean function

- Two functions equivalent if and only if graphs isomorphic
- Desirable property: *simplest form is canonical.*

- 4 -

## Representing Circuit Functions

### Functions

- All outputs of 4-bit adder
- Functions of data inputs

### Shared Representation

- Graph with multiple roots
- 31 nodes for 4-bit adder
- 571 nodes for 64-bit adder
- Linear growth

- 5 -

## Effect of Variable Ordering

$$(a_1 \wedge b_1) \vee (a_2 \wedge b_2) \vee (a_3 \wedge b_3)$$

### Good Ordering

Linear Growth

### Bad Ordering

Exponential Growth

- 6 -

## Symbolic Boolean Manipulation with OBDDs

### Sample Function Classes

Function Class	Best	Worst	Ordering Sensitivity
ALU (Add/Sub)	linear	exponential	High
Symmetric	linear	quadratic	None
Multiplication	exponential	exponential	Low

#### General Experience

- Many tasks have reasonable OBDD representations
- Algorithms remain practical for up to 500,000 node OBDDs
- Heuristic ordering methods generally satisfactory

- 7 -

## Symbolic Manipulation with OBDDs

#### Strategy

- Represent data as set of OBDDs
  - Identical variable orderings
- Express solution method as sequence of symbolic operations
  - Sequence of constructor & query operations
  - Similar style to on-line algorithm
- Implement each operation by OBDD manipulation
  - Do all the work in the constructor operations

#### Key Algorithmic Properties

- Arguments are OBDDs with identical variable orderings
- Result is OBDD with same ordering
- Each step polynomial complexity

- 8 -

## If-Then-Else Operation

### Concept

- Basic technique for building OBDD from logic network or formula.

### Arguments $I, T, E$

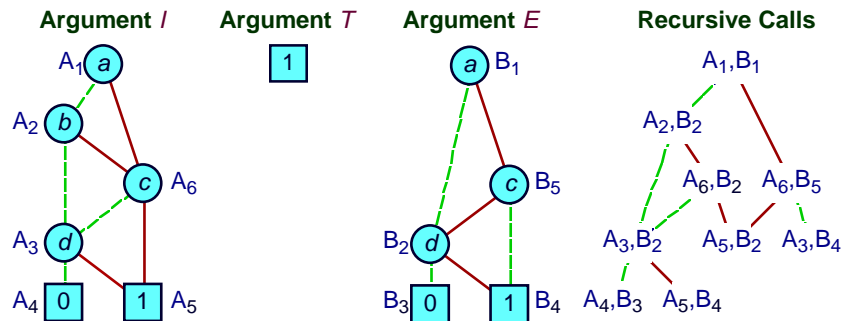

- Functions over variables  $X$
- Represented as OBDDs

### Result

- OBDD representing composite function
- $(I \wedge T) \vee (\neg I \wedge E)$

- 9 -

## If-Then-Else Execution Example

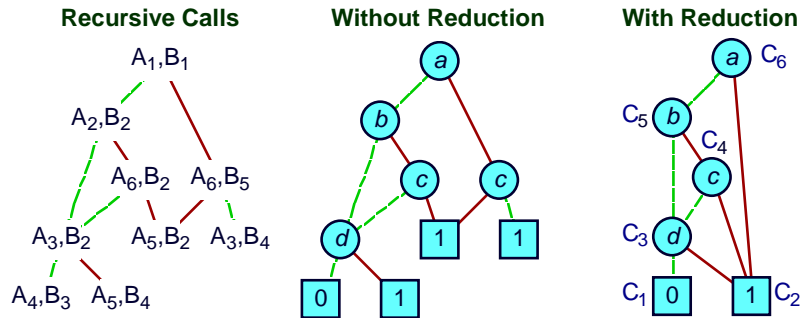

### Optimizations

- Dynamic programming
- Early termination rules

- 10 -

## If-Then-Else Result Generation

- Recursive calling structure implicitly defines unreduced BDD
- Apply reduction rules bottom-up as return from recursive calls

- 11 -

## Restriction Operation

### Concept

- Effect of setting function argument  $x_i$  to constant  $k$  (0 or 1).
- Also called Cofactor operation (UCB)

$F_{\bar{x}}$  equivalent to  $F[x = 1]$

$F_x$  equivalent to  $F[x = 0]$

- 12 -

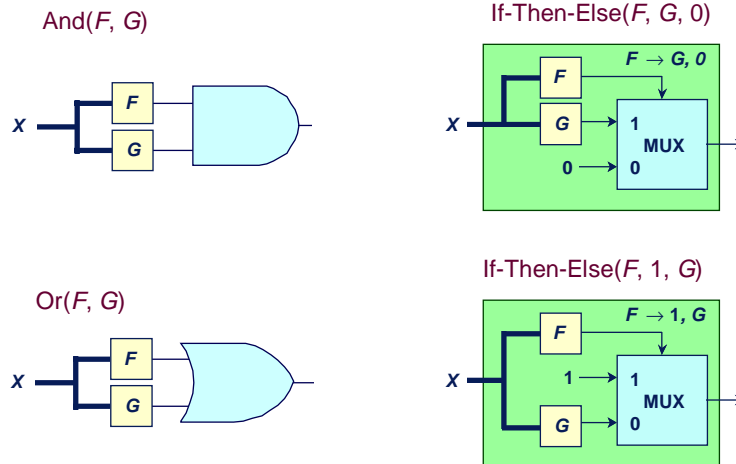

## Restriction Execution Example

- 13 -

## Derived Algebraic Operations

- Other operations can be expressed in terms of If-Then-Else

- 14 -

## Generating OBDD from Network

**Task:** Represent output functions of gate network as OBDDs.

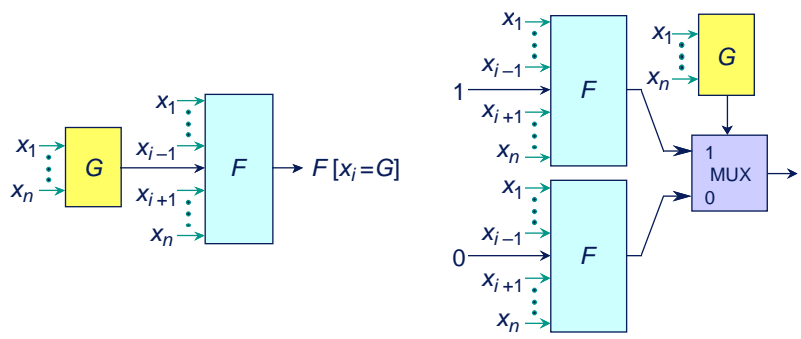

**Evaluation**

```

A ← new_var ("a");
B ← new_var ("b");
C ← new_var ("c");
T1 ← And (A, 0, B);
T2 ← And (B, C);
Out ← Or (T1, T2);
    
```

## Functional Composition

- Create new function by composing functions F and G.
- Useful for composing hierarchical modules.

## Variable Quantification

- Eliminate dependency on some argument through quantification
- Combine with AND for universal quantification.

- 17 -

## Finite State System Analysis

### Systems Represented as Finite State Machines

- Sequential circuits
- Communication protocols
- Synchronization programs

### Analysis Tasks

- State reachability
- State machine comparison
- Temporal logic model checking

### Traditional Methods Impractical for Large Machines

- Polynomial in number of states
- Number of states exponential in number of state variables.
- Example: single 32-bit register has 4,294,967,296 states!

- 18 -

## Temporal Logic Model Checking

### Verify Reactive Systems

- Construct state machine representation of reactive system
  - Nondeterminism expresses range of possible behaviors
  - “Product” of component state machines
- Express desired behavior as formula in temporal logic
- Determine whether or not property holds

- 19 -

## Characteristic Functions

### Concept

- $A \subseteq \{0,1\}^n$ 
  - Set of bit vectors of length  $n$
- Represent set  $A$  as Boolean function  $A$  of  $n$  variables
  - $X \in A$  if and only if  $A(X) = 1$

### Set Operations

- 20 -

## Symbolic FSM Representation

Nondeterministic FSM

Symbolic Representation

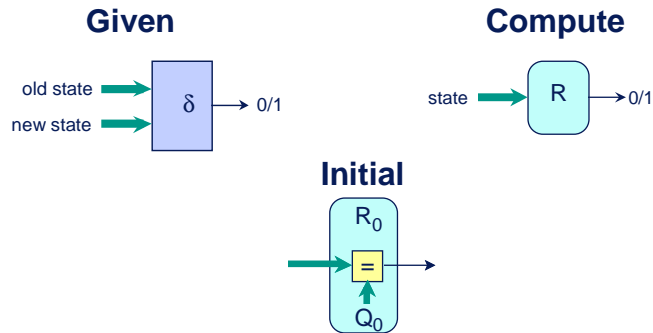

- Represent set of transitions as function  $\delta(Old, New)$ 
  - Yields 1 if can have transition from state *Old* to state *New*
- Represent as Boolean function
  - Over variables encoding states

- 21 -

## Reachability Analysis

### Task

- Compute set of states reachable from initial state  $Q_0$
- Represent as Boolean function  $R(S)$
- Never enumerate states explicitly

- 22 -

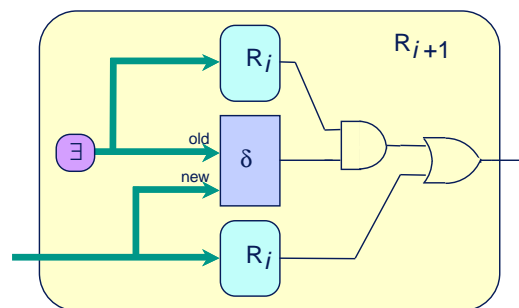

## Breadth-First Reachability Analysis

- $R_i$  – set of states that can be reached in  $i$  transitions
- Reach fixed point when  $R_n = R_{n+1}$ 
  - Guaranteed since finite state

– 23 –

## Iterative Computation

- $R_{i+1}$  – set of states that can be reached  $i+1$  transitions
  - Either in  $R_i$
  - or single transition away from some element of  $R_i$

– 24 –

## Symbolic FSM Analysis Example

- K. McMillan, E. Clarke (CMU) J. Schwalbe (Encore Computer)

### Encore Gigamax Cache System

- Distributed memory multiprocessor
- Cache system to improve access time
- Complex hardware and synchronization protocol.

### Verification

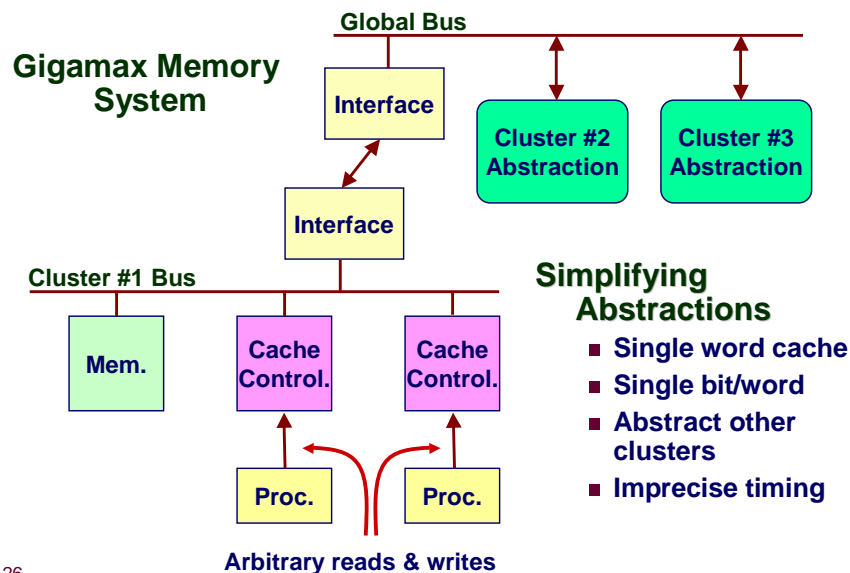

- Create “simplified” finite state model of system ( $10^9$  states!)
- Verify properties about set of reachable states

### Bug Detected

- Sequence of 13 bus events leading to deadlock
- With random simulations, would require  $\approx 2$  years to generate failing case.
- In real system, would yield MTBF < 1 day.

- 25 -

## System Modeling Example

- 26 -

## Commercial Applications of Symbolic Model Checking

### Several Commercial Tools

- Difficult training and customer support

### Most Large Companies Have In-House Versions

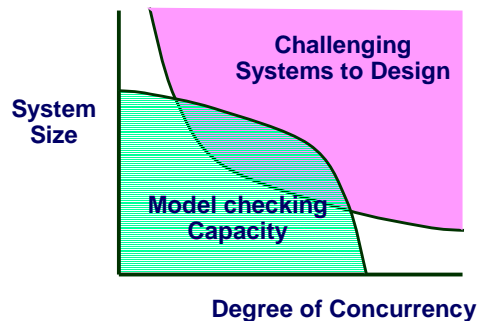

- IBM, Lucent, Intel, Motorola, SGI, Fujitsu, Siemens, ...
- Many based on McMillan's SMV program

### Requires Sophistication

- Beyond that of mainstream designers

- 27 -

## Application Challenge

### Cannot Apply Directly to Full Scale Design

- Verify smaller subsystems
- Verify abstracted versions of full system
  - Must understand system & tool to do effectively

- 28 -

### Real World Issues

#### Still Too Volatile

- Fail by running out of space
- Useless once exceed physical memory capacity

#### Ongoing Research to Improve Memory Performance

- Dynamic variable ordering
- Exploiting modularity of system model
  - Partitioned transition relations
- Exploiting parallelism
  - Map onto multiple machines
  - Difficult program for parallel computation
    - » Dynamic, irregular data structures

- 29 -

### Dynamic Variable Reordering

- Richard Rudell, Synopsys

#### Periodically Attempt to Improve Ordering for All BDDs

- Part of garbage collection
- Move each variable through ordering to find its best location

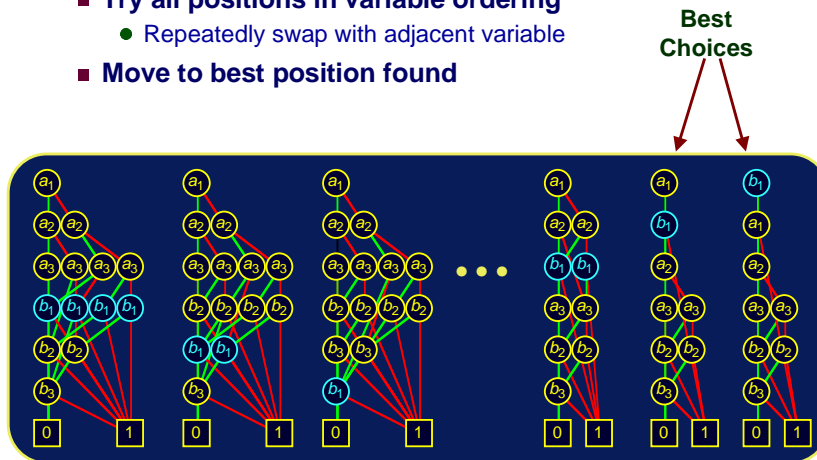

#### Has Proved Very Successful

- Time consuming but effective
- Especially for sequential circuit analysis

- 30 -

## Dynamic Reordering By Sifting

- Choose candidate variable
- Try all positions in variable ordering
  - Repeatedly swap with adjacent variable
- Move to best position found

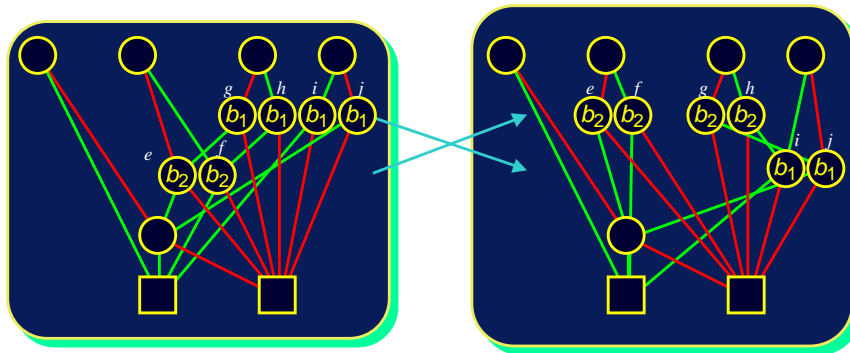

- 31 -

## Swapping Adjacent Variables

### Localized Effect

- Add / delete / alter only nodes labeled by swapping variables
- Do not change any incoming pointers

- 32 -

## Tuning of BDD Packages

### Cooperative Effort

- Bwolen Yang, in cooperation with researchers from Colorado, Synopsys, CMU, and T.U. Eindhoven
- Measure & improve performance of BDDs for symbolic model checking

### Methodology

- Generated set of benchmark traces
- Run 6 different packages on same machine
- Compare results and share findings
  - Cooperative competition

- 33 -

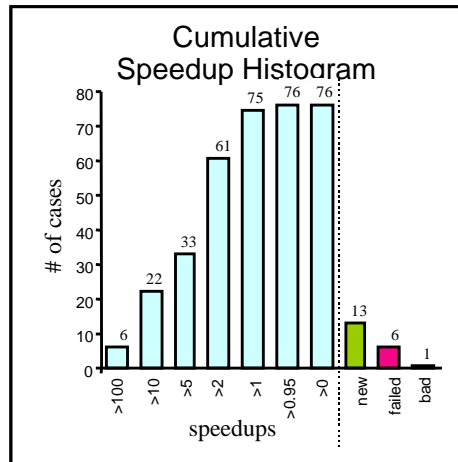

## Effect of Optimizations

### Compare pre- vs. post-optimized results for 96 runs

- 6 different BDD packages
- 16 benchmark traces each
- Limit each run to maximum of 8 CPU hours and 900 MB
- Measure speedup =  $T_{old} / T_{new}$  or:
  - New: Failed before but now succeeds
  - Fail: Fail both times
  - Bad: Succeeded before, but now fails

- 34 -

## Optimization Results Summary

- 35 -

## What's Good about OBDDs

### Powerful Operations

- Creating, manipulating, testing
- Each step polynomial complexity
  - Graceful degradation

### Generally Stay Small Enough

- Especially for digital circuit applications
- Given good choice of variable ordering

### Weak Competition

- No other method comes close in overall strength
- Especially with quantification operations

- 36 -

## Thoughts on Algorithms Research

### Need to be Willing to Attack Intractable Problems

- Many real-world problems NP-hard
- No approximations for verification

### Who Works on These?

- Mostly people in application domain
  - Most work on BDDs in computer-aided design conferences
- Not by people with greatest talent in algorithms
  - No papers in STOC/FOCS/SODA
  - Probably many ways they could improve things
- Fundamental dilemma
  - Can only make weak formal statements about efficiency
  - Utility demonstrated empirically
