

15-494/694: Cognitive Robotics

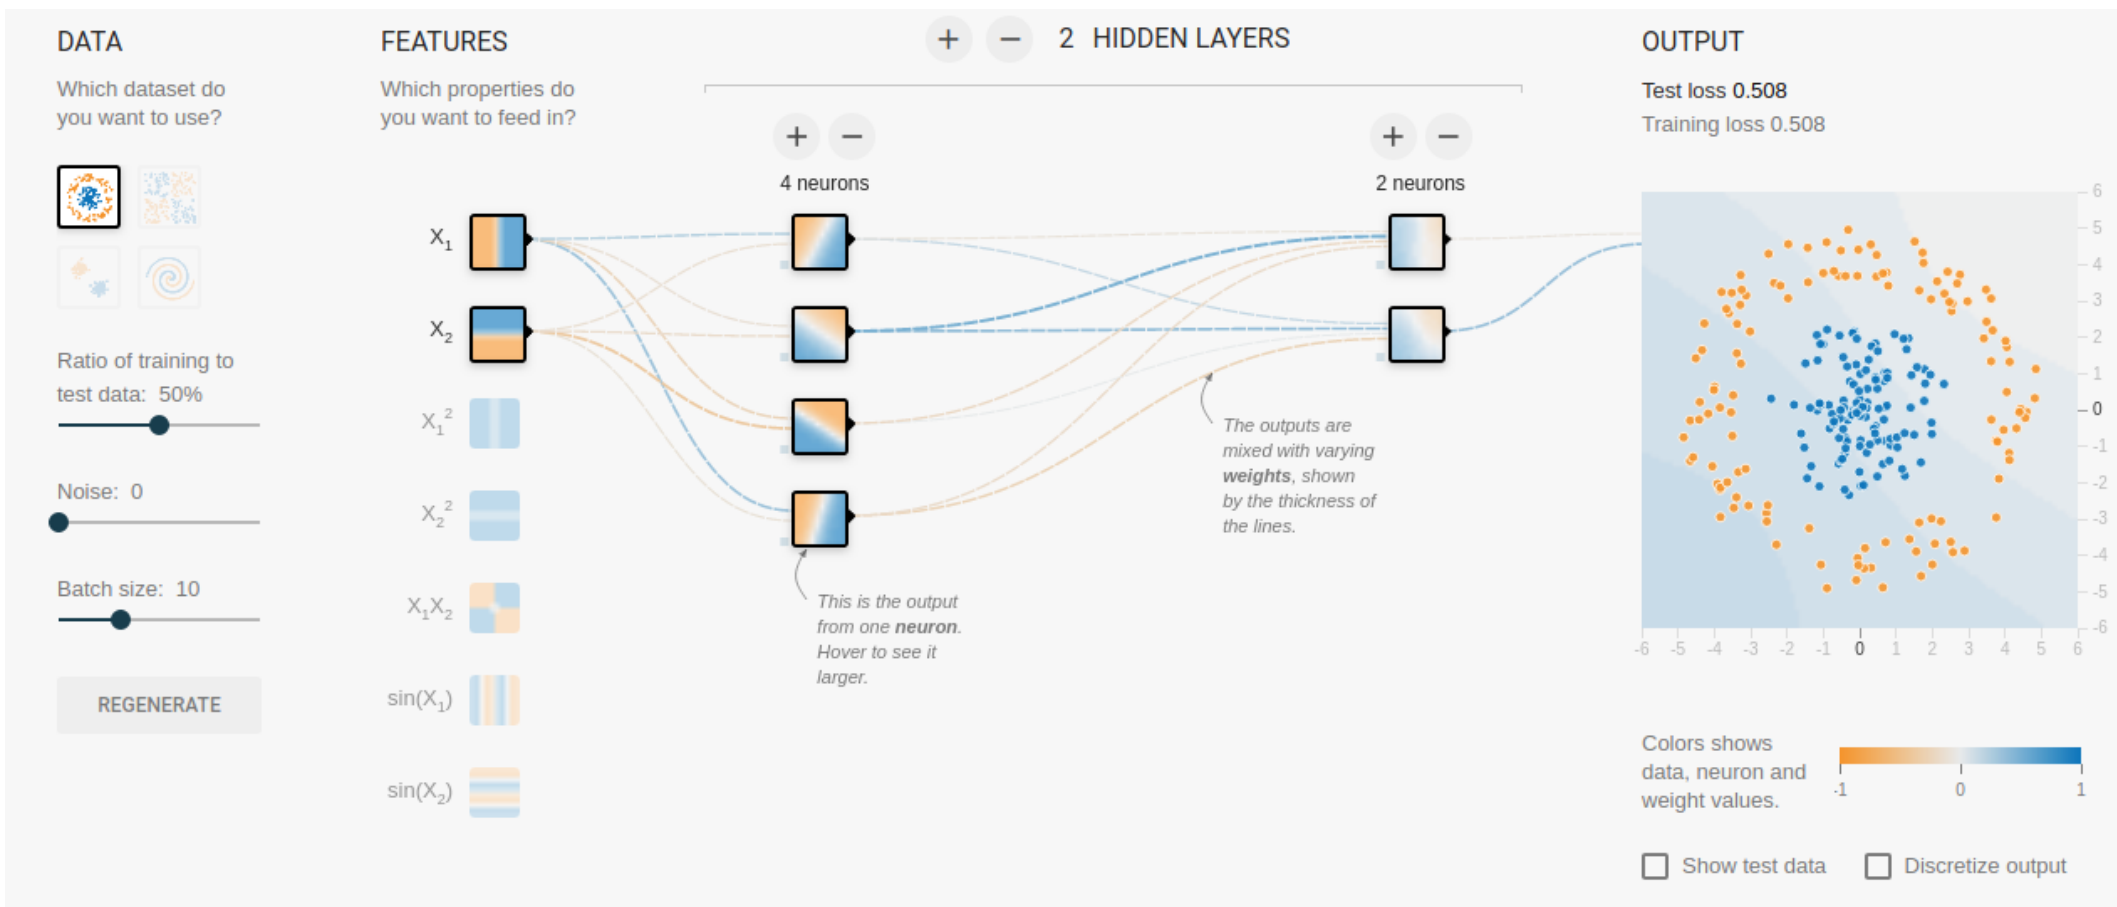

Dave Touretzky

Lecture 13:
Convolutional Neural Nets

TensorFlow Playground

Google's interactive backprop simulator.
<https://playground.tensorflow.org>

MNIST Dataset

- 60,000 labeled handwritten digits
- 28 x 28 pixel grayscale images

Recognition With a Linear Network

PyTorch

- Python package for tensor manipulation and vectorized computations, including neural net learning.
 - Replacement for numpy
 - Optimized for GPUs
- Tensors are multi-dimensional arrays, similar to numpy's ndarray structure.
- Code can run on either CPU or GPU.

Defining the Model mnist1

```
class MultiLogisticModel(nn.Module):  
  
    def __init__(self, in_dim, out_dim):  
        super(MultiLogisticModel, self).__init__()  
        self.linear = nn.Linear(in_dim, out_dim)  
  
    def forward(self, x):  
        out = self.linear(x)  
        return out
```

```
model = MultiLogisticModel(28*28, 10)
```

Learned Weights to Output Units

Training set performance: 89% correct.

Batch Size

- An *epoch* is one pass through all the training data.
- With a large training set (60,000 images), we don't need to see all the training examples in order to estimate the error gradient.
- We set a batch size of 100 to indicate we want to do a weight update after every 100 training examples.
 - The examples need to be mixed together.
 - What if we trained on all the 2's first?

Adding A Hidden Layer

Batch Normalization

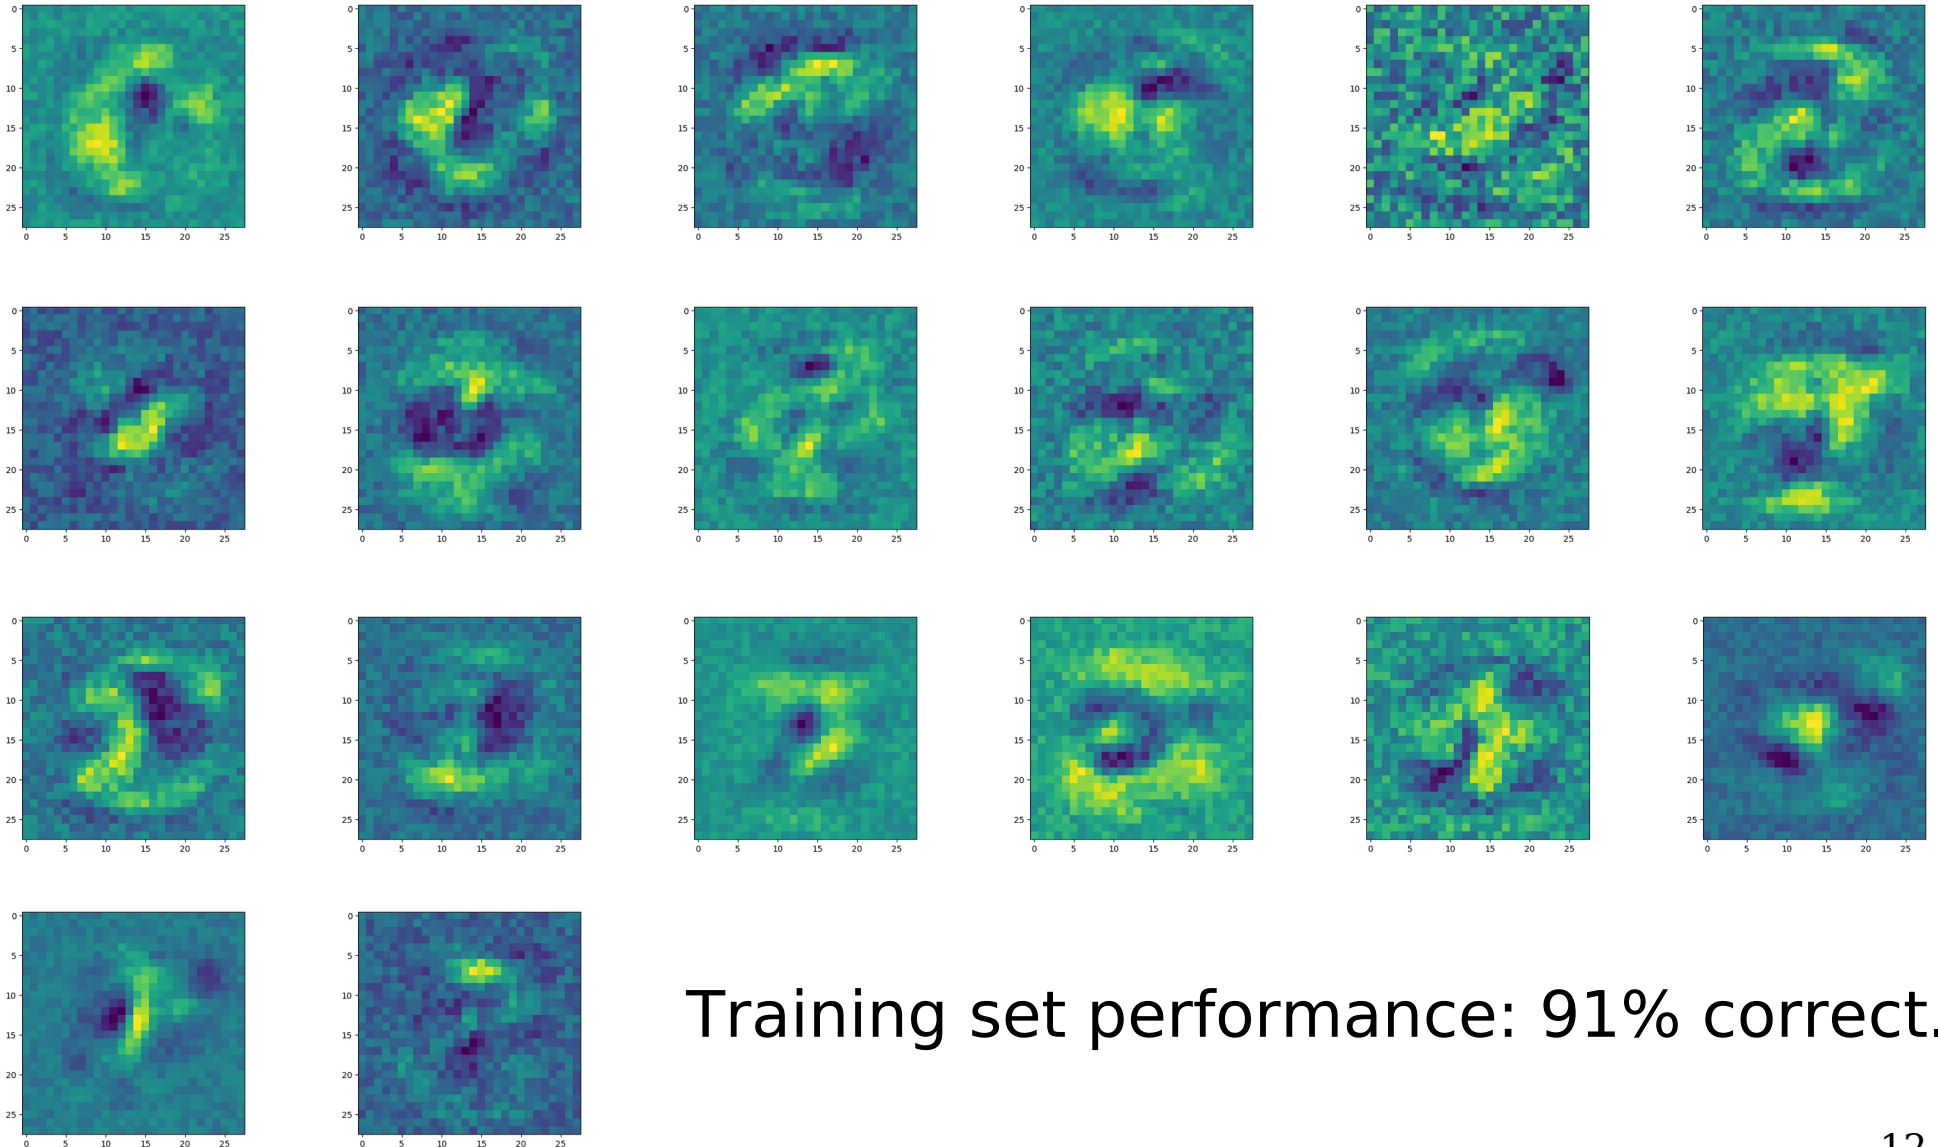

- We want the activity patterns in each layer to have nice statistical properties (mean and variance) because this helps speed up learning.
- But each weight update changes the statistical distribution.
- Solution: “batch normalization”, a trick for making the distributions more uniform.
- Built in to PyTorch.

Defining the Model mnist2

```
class OneHiddenLayer(nn.Module):  
  
    def __init__(self, in_dim, out_dim, nhiddens):  
        super(OneHiddenLayer, self).__init__()  
        self.network = nn.Sequential(  
            nn.Linear(in_dim, nhiddens),  
            nn.BatchNorm1d(nhiddens),  
            nn.ReLU(),  
            nn.Linear(nhiddens, out_dim)  
        )  
  
    def forward(self, x):  
        out = self.network(x)  
        return out
```

```
model = OneHiddenLayer(28*28, 10, 20)
```

Learned Weights to Hidden Units

Training set performance: 91% correct.

Learned Weights to Output Units

Training set performance: 91% correct.

Overfitting

How to Avoid Overfitting

- Increase the size of the training set.
- Reduce the number of parameters:
 - Fewer hidden units
 - Shared weights (convolutional network)
- Regularization: penalize large weights to encourage making more weights be zero.
- Dropout: randomly disable some fraction of the units on every iteration.
- Early stopping:
 - Maintain a separate cross-validation set
 - Stop training when the CV error rises

Convolutional Neural Networks

- Learn small (3x3 or 5x5) feature detectors or *kernels* that can be applied anywhere in the image.

Feature 1:

Feature 2:

Feature Maps

28 x 28 image

32 feature maps
26 x 26

32 kernels
5x5 pixels
stride 1
padding 1

weights = $32 \times (5 \times 5 + 1) = 832$ (small!)

connections = $32 \times (26 \times 26) \times (5 \times 5 + 1) = 562,432$

Stride 1

Stride 2

First Kernel: Padding 0

First Kernel: Padding 1

First Kernel: Padding 2

Max Pooling

- We might not care exactly where a feature appears in the image.
- Downsampling by max pooling reduces the number of units and connections.

Choice of Activation Function

- Sigmoid and tanh were popular early on:

- Now it's more common to use ReLU:
Rectified Linear Unit. $g(x) = \max(x, 0)$
 - Derivative doesn't go to zero for large x.

Choice of Loss Function

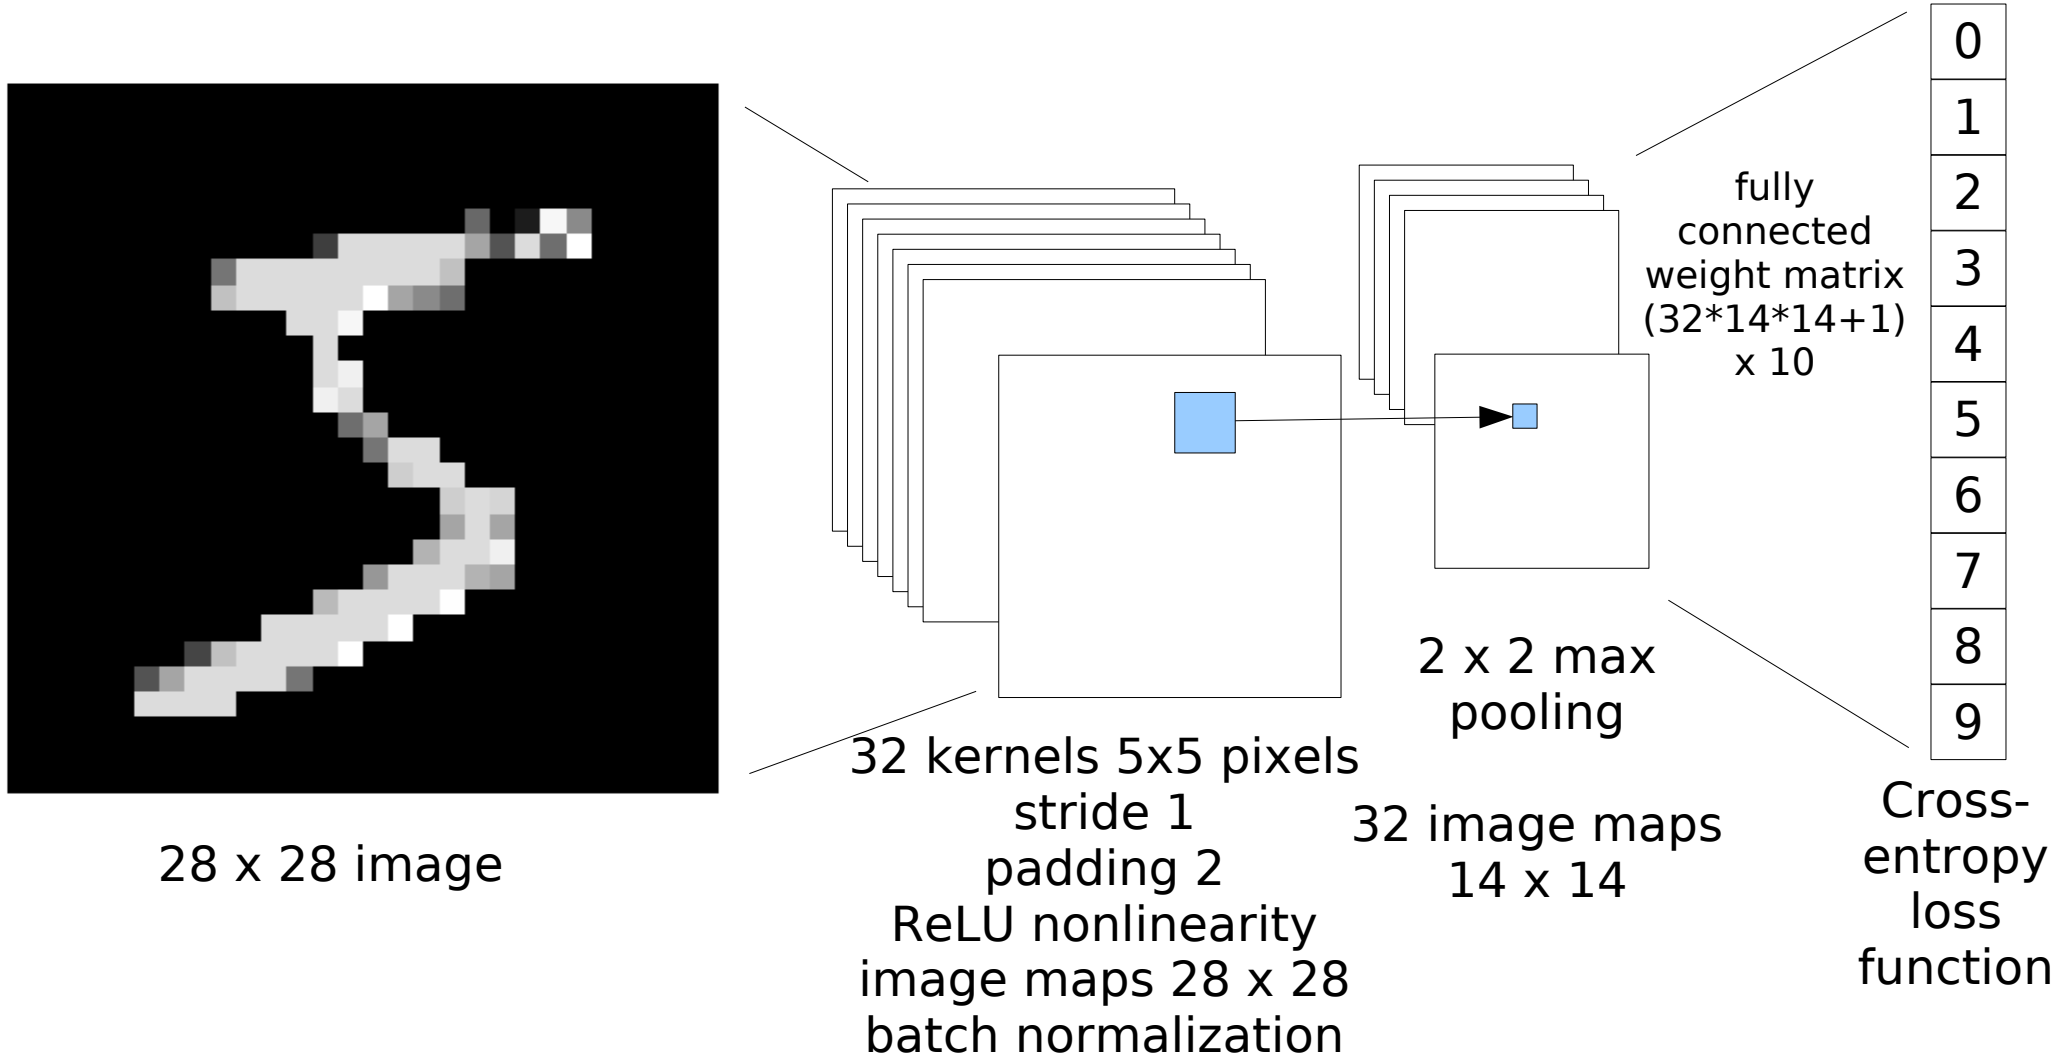

- Mean Squared Error is a general loss function but not always the best to use.

$$E = \frac{1}{2P} \sum_p (d^p - y^p)^2$$

- If desired outputs are probabilities (values between 0 and 1), use cross-entropy instead. Heavily penalizes really wrong outputs.

$$E = \sum_p -d^p \log(y^p) - (1 - d^p) \log(1 - y^p)$$

MNIST With A CNN

parameters = 63,626
How many connections?

Accuracy on training set: 98.7%

Defining the Model mnist3

```
class OneConvLayer(nn.Module):  
  
    def __init__(self, in_dim, out_dim, nkernels):  
        super(OneConvLayer, self).__init__()  
        self.network1 = nn.Sequential(  
            nn.Conv2d(in_channels=1,  
                    out_channels=nkernels,  
                    kernel_size=5,  
                    stride=1,  
                    padding=2),  
            nn.BatchNorm2d(nkernels),  
            nn.ReLU(),  
            nn.MaxPool2d(kernel_size=2)  
        )  
        self.network2 = nn.Linear(nkernels*14*14,  
                                  out_dim)
```

Defining mnist3 (cont.)

```
def forward(self, x):  
    out = self.network1(x)  
    out = out.view(out.size(0), -1)  
    out = self.network2(out)  
    return out
```

```
model = OneConvLayer(28*28, 10, 32)
```

Sample Learned Kernels (32 Total)

Deep Neural Networks

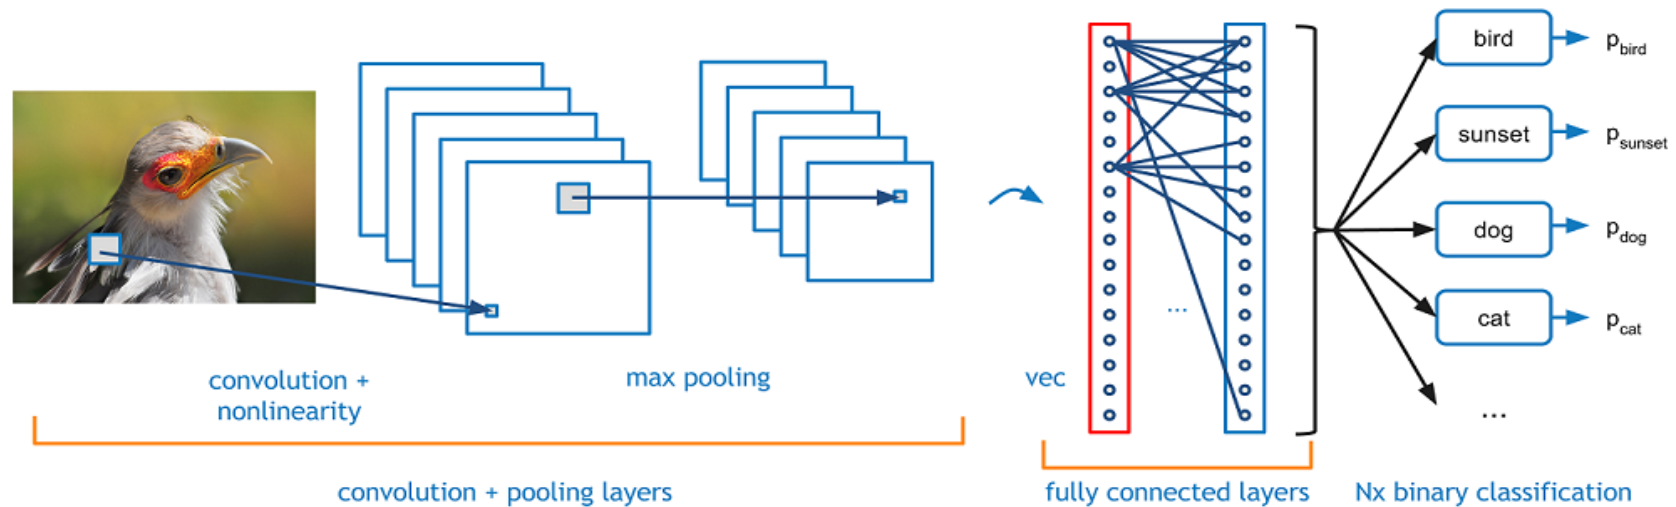

- For really hard problems (e.g., object recognition on color images) we may need many layers.
- Series of convolutional and max pooling layers, followed by some fully connected layers.
 - LeNet had 10 layers.
 - Inception V1 had 27 layers.
 - ResNet has 100 layers.
- GPUs required for training.

LeNet (Yann LuCun, 1990s)

- Handwritten digit recognition

Conv & Pool Key: kernelType [kw,hw,inchan]/stride × outchan
Layer Dimension Key: width × height × channels

Purple: Full Convolution
Dark Blue: Depthwise Convolution
Light Blue: Pointwise Convolution
Orange: Max Pooling

Layer depths are drawn with logarithmic scaling. Max pooling layer widths and heights are shrunk by $\frac{1}{4}$ instead of $\frac{1}{2}$.
