

Assignment 2: Parallel Branch-and-Bound  
for the Wandering Salesman Problem

Assigned: Thursday, Feb. 7  
Due: Thursday, Feb. 21, noon

## 1 Policy and Logistics

Please work in groups of 2 people to solve the problems for this assignment. (Hand in one assignment per group.) There will be both electronic and hard copy hand-ins, as described below. Any clarifications and revisions to the assignment will be posted on the “*Assignments and exam information*” web page in the class WWW directory. In the following, *HOMEDIR* refers to the directory:

`/afs/cs.cmu.edu/academic/class/15418-s08/public`

and *ASSTDIR* refers to the subdirectory `HOMEDIR/asst/asst2`.

## 2 General Information

In this assignment you will be solving the Wandering Salesman Problem (WSP) using the Branch-and-Bound technique. WSP is representative of combinatorial optimization problems. The Branch-and-Bound technique is an exhaustive evaluation technique that tries to make use of knowledge of the underlying problem to reduce the amount of computation.

## 3 The Wandering Salesman Problem

The object of WSP is to find the shortest route for a traveling salesman so that the salesman visits every one of a set of cities exactly once. (Note: the salesman doesn't return home. This is the difference between the wandering salesman problem and the traveling salesman problem.) This is a hard combinatorial optimization problem since for  $N$  cities there are at most  $(N-1)!$  possible routes (we assume that the cities are fully connected).

The input to the problem is given in the form of a matrix. An element of the matrix,  $d[i][j]$  gives the distance between city  $i$  and city  $j$ . The input to your program should be a file organized as follows:

```
N
d[1][2]
d[1][3] d[2][3]
d[1][4] d[2][4] d[3][4]
.
.
.
d[1][N] d[2][N] d[3][N] ... d[N-1][N]
```

where  $N$  is the number of cities, and  $d[i][j]$  is an integer giving the distance between cities  $i$  and  $j$ . The output from the program should be an ordered list of cities (numbers between 1 and  $N$ ). Clearly, there are 2 equivalent permutations - either one is acceptable.

## 4 Branch-and-Bound Solutions to Combinatorial Optimization Problems

First, consider a simple exhaustive evaluation as a way of solving the WSP. One way you might think about evaluating every possible route is to construct a tree that describes all of the possible routes from the first city, as shown in Figure 1 for a four city example.

Figure 1: A WSP example

For this WSP,  $d[1][2] = 5$ ,  $d[1][3] = 40$ ,  $d[1][4] = 11$ ,  $d[2][3] = 9$ ,  $d[2][4] = 6$ ,  $d[3][4] = 8$ . All of the possible routes can be found by traveling from the root to a different leaf node three times, once for each unique path and then back to the root. For example, by taking the middle branch from the root node and the right branch after that, the route  $1 \rightarrow 3 \rightarrow 4 \rightarrow 2$  is produced, and has a distance of  $40+8+6 = 54$ . There are six unique root to leaf paths in this tree. Each possible route is represented twice, once in each direction.

A simple exhaustive evaluation of WSP for this example would then be to follow the six root to leaf paths and determine the total distance for each path by adding up the distances indicated by each edge in the tree and then adding the distance back to the root. The route with the smallest distance is then chosen.

A better way to traverse each tree is to do it recursively. Here the summation of the earlier parts of each route is not repeated every time that route portion is reused in several routes. The Branch-and-Bound approach uses this type of problem formulation, but with some added intelligence. It uses more knowledge of the problem to prune the tree as much as possible so that less evaluation is necessary. The basic approach works as follows:

1. Evaluate one route of the tree in its entirety, (say  $1 \rightarrow 2 \rightarrow 3 \rightarrow 4$ ) and determine the distance of that path. Call this distance the current “bound” of the problem. The bound for this path in the above tree is  $5 + 9 + 8 = 22$ .
2. Next, suppose that a second path is partially evaluated, say path  $1 \rightarrow 3$ , and the partial distance, 40, is already greater than the *bound*. If that is the case, then there is no need to complete the traversal of any part of the tree from there on, because all of those possible routes (in this case there are two)

must have a distance greater than the bound. In this way the tree is *pruned* and therefore does not have to be entirely traversed.

3. Whenever any route is discovered that has a better distance than the current bound, then the bound is updated to this new value.

The Branch-and-Bound approach always remembers the best path it has found so far, and uses that to prevent search down parts of the tree that couldn't possibly produce better routes. You can see that for larger trees, this could result in the removal of many possible evaluations.

## 5 The Assignment

The assignment is to write a parallel Branch-and-Bound program for the WSP, using OpenMP on the NCSA *cobalt* machine and the PSC *rachel* machine. The objective is to obtain the best speedup possible. You should use the input format described above. You should have a command-line argument that specifies the number of processors to use. In addition, a command-line argument should also give the name of the input file.

Your report should include the following items:

1. A brief (roughly one or two pages) description of how your program works. Describe the general program flow and all significant data structures.
2. The solution to the problem given in `HOMEDIR/asst/asst2/input/distances`. This file contains a 16 city problem. (Hint: for debugging purposes, you may want to use some of the smaller input files included in the same directory.)
3. Execution time and speedup (both total and computation) for 1, 2, 4, 8, 16, 24, and 32 processors on the NCSA *cobalt* machine, and 1, 2, 4, and 8 processors on the PSC *rachel* machine. (If you can get even more processors, that is great.)
4. Discuss the results you expected and explain the reasons for any non-ideal behavior you observe. In particular, if you don't get perfect speedup, explain why. Is it possible to get better than perfect speedup? Give measurements to back up your explanations.
5. Compare your results on the two machines. If you see different behaviors on *cobalt* versus *rachel*, please discuss what you think is the likely cause of the different behaviors.

If the execution time for your program takes more than a few minutes, double-check your program and algorithm. Make sure your programs run on a uniprocessor before trying to run them in parallel. Also, debug your programs using smaller numbers of cities (perhaps `HOMEDIR/asst/asst2/input/dist4`) and small numbers of processors before trying larger runs.

## 6 Hand-in

### Electronic submission:

Your solution to the WSP. Do this by naming your file *last-wsp.c*, where *last* is the last name of one of your group members, and copying this file to the directory

Include as comments near the beginning of this file the identities of all members of your group. Also remember to put comments in your code.

**Hard-copy submission:**

1. Answers to the questions listed in Section 5.
2. A listing of your code.
