Parallel Programming: Overview

Todd C. Mowry CS 418 January 18-19, 2011

Why Bother with Programs?

They're what runs on the machines we design

- · Helps make design decisions
- · Helps evaluate systems tradeoffs

Led to the key advances in uniprocessor architecture

· Caches and instruction set design

More important in multiprocessors

- · New degrees of freedom
- · Greater penalties for mismatch between program and architecture

- 2 - CS 418

Important for Whom?

Algorithm designers

· Designing algorithms that will run well on real systems

Programmers

· Understanding key issues and obtaining best performance

Architects

- Understand workloads, interactions, important degrees of freedom
- · Valuable for design and for evaluation

= - 3 - CS 418 :

Next 3 Sections of Class: Software

- 1. Parallel programs
 - · Process of parallelization
 - · What parallel programs look like in major programming models
- 2. Programming for performance
 - \cdot Key performance issues and architectural interactions
- 3. Workload-driven architectural evaluation
 - · Beneficial for architects and for users in procuring machines

Unlike on sequential systems, can't take workload for granted

- \cdot Software base not mature; evolves with architectures for performance
- · So need to open the box

Let's begin with parallel programs ...

4 - CS 418

Outline

Motivating Problems (application case studies)

Steps in creating a parallel program

What a simple parallel program looks like

- · In the three major programming models
- · What primitives must a system support?

Later: Performance issues and architectural interactions

= - 5 - CS 418

Motivating Problems

Simulating Ocean Currents

· Regular structure, scientific computing

Simulating the Evolution of Galaxies

· Irregular structure, scientific computing

Rendering Scenes by Ray Tracing

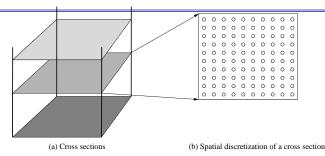

· Irregular structure, computer graphics

Data Mining

- · Irregular structure, information processing
- · Not discussed here (read in book)

6 - CS 418

Simulating Ocean Currents

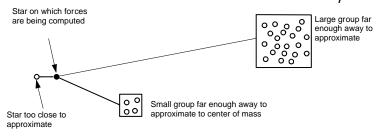

- · Model as two-dimensional grids
- · Discretize in space and time
 - finer spatial and temporal resolution -> greater accuracy
- · Many different computations per time step
 - set up and solve equations
- · Concurrency across and within grid computations

-7- CS 418 =

Simulating Galaxy Evolution

- · Simulate the interactions of many stars evolving over time
- · Computing forces is expensive
- · O(n2) brute force approach
- · Hierarchical Methods take advantage of force law: $G \frac{m_1 m_2}{r^2}$

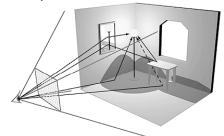

· Many time-steps, plenty of concurrency across stars within one

8 - CS 418

Rendering Scenes by Ray Tracing

- · Shoot rays into scene through pixels in image plane
- · Follow their paths
 - they bounce around as they strike objects
 - they generate new rays: ray tree per input ray
- · Result is color and opacity for that pixel
- · Parallelism across rays

All case studies have abundant concurrency

= CS 418

Creating a Parallel Program

Assumption: Sequential algorithm is given

· Sometimes need very different algorithm, but beyond scope

Pieces of the job:

- · Identify work that can be done in parallel
- · Partition work and perhaps data among processes
- · Manage data access, communication and synchronization
- · Note: work includes computation, data access and I/O

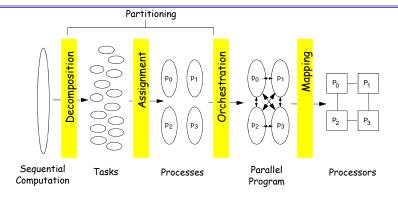

Main goal: Speedup (plus low prog. effort and resource needs)

Speedup (p) = $\frac{Performance(p)}{Performance(1)}$

For a fixed problem:

Speedup (p) = $\frac{Time(1)}{Time(p)}$

Steps in Creating a Parallel Program

- 4 steps: Decomposition, Assignment, Orchestration, Mapping
 - · Done by programmer or system software (compiler, runtime, ...)
 - · Issues are the same, so assume programmer does it all explicitly

= - 11 - CS 418 =

Some Important Concepts

Task:

- · Arbitrary piece of undecomposed work in parallel computation
- · Executed sequentially; concurrency is only across tasks
- · E.g. a particle/cell in Barnes-Hut, a ray or ray group in Raytrace
- · Fine-grained versus coarse-grained tasks

Process (thread):

- · Abstract entity that performs the tasks assigned to processes
- · Processes communicate and synchronize to perform their tasks

Processor:

- · Physical engine on which process executes
- · Processes virtualize machine to programmer
 - first write program in terms of processes, then map to processors

- 12 - _____ CS 418

Decomposition

Break up computation into tasks to be divided among processes

· i.e. identify concurrency and decide level at which to exploit it

Tasks may or may not be defined statically:

- · tasks may become available dynamically
- · # of available tasks may vary with time

Goal: Enough tasks to keep processes busy, but not too many

 \cdot # of tasks available at a time is upper bound on achievable speedup

= - 13 - _____ CS 418 =

Limited Concurrency: Amdahl's Law

- · Fundamental limitation on parallel speedup
- If s = fraction of sequential execution that is inherently serial

then speedup ≤ 1/s

- 14 - CS 418

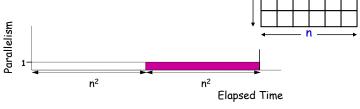

Amdahl's Law Example

- 2-phase computation over an n-by-n grid:
 - Phase 1: perform an independent computation on each grid element
 easy to parallelize
 - · Phase 2: add a value from each grid element into a global sum

- more difficult to parallelize; serial by default

Sequential Execution:

· both phases take n² time; 2n² total

- 15 - ----

— CS 418 =

First Attempt at Parallelization

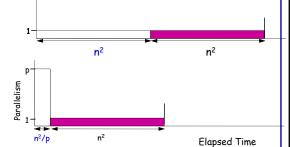

Strategy:

- · Phase 1: execute in parallel
 - time for phase $1 = n^2/p$
- · Phase 2: execute serially
 - time for phase $2 = n^2$

Overall Performance:

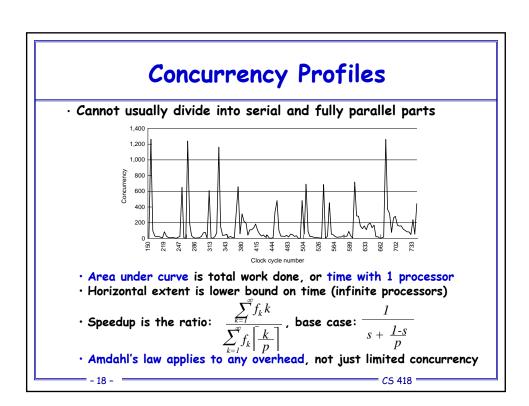

· i.e. no more than 2

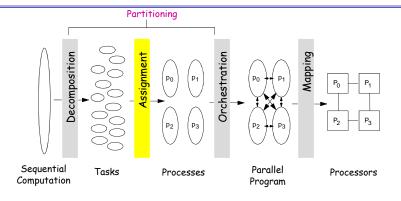

16 -

= CS 41

Parallelizing Phase 2 Trick: divide second phase into two steps • Step 1: accumulate into private sum during sweep • Step 2: add per-process private sum into global sum Overall Performance: • Parallel time = $n^2/p + n^2/p + p$ • Speedup <= $p2n^2 \over 2n^2 + p^2$ close to p if n>>p Elapsed Time

Steps in Creating a Parallel Program

4 steps: Decomposition, Assignment, Orchestration, Mapping

- 19 - CS 418 =

Assignment

Specifying mechanism to divide work up among processes

- \cdot e.g. which process computes forces on which stars, or which rays
- · Together with decomposition, also called partitioning
- · Goals: balance workload, reduce communication and management cost

Structured approaches usually work well

- · Code inspection (parallel loops) or understanding of application
- · Well-known heuristics
- · Static versus dynamic assignment

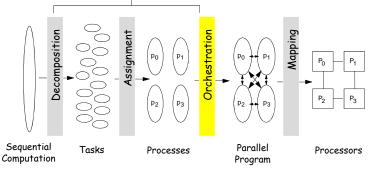

As programmers, we worry about partitioning first

- · Usually independent of architecture or prog model
- · But cost and complexity of using primitives may affect decisions

As architects, we assume program does reasonable job of it

= - 20 - _____ CS 418

Steps in Creating a Parallel Program Partitioning Partitioning

4 steps: Decomposition, Assignment, Orchestration, Mapping

- 21 - CS 418 =

Orchestration

- · Naming data
- · Structuring communication
- · Synchronization
- · Organizing data structures and scheduling tasks temporally

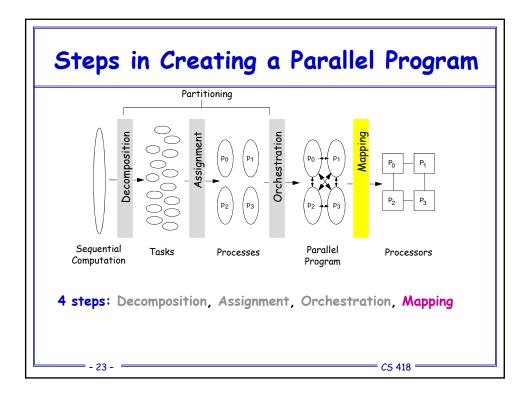

Goals

- · Reduce cost of communication and synch. as seen by processors
- \cdot Preserve locality of data reference (incl. data structure organization)
- \cdot Schedule tasks to satisfy dependences early
- · Reduce overhead of parallelism management

Closest to architecture (and programming model & language)

- · Choices depend a lot on comm. abstraction, efficiency of primitives
- · Architects should provide appropriate primitives efficiently

- 22 - ______ CS 418

Mapping

After orchestration, already have parallel program

Two aspects of mapping:

- · Which processes will run on same processor, if necessary
- · Which process runs on which particular processor
 - mapping to a network topology

One extreme: space-sharing

- · Machine divided into subsets, only one app at a time in a subset
- \cdot Processes can be pinned to processors, or left to OS

Another extreme: complete resource management control to OS

· OS uses the performance techniques we will discuss later

Real world is between the two

· User specifies desires in some aspects, system may ignore

Usually adopt the view: process <-> processor

= - 24 - _____ CS 418

Parallelizing Computation vs. Data

Above view is centered around computation

· Computation is decomposed and assigned (partitioned)

Partitioning data is often a natural view too

- · Computation follows data: owner computes
- · Grid example; data mining; High Performance Fortran (HPF)

But not general enough

- · Distinction between comp. and data stronger in many applications
 - Barnes-Hut, Raytrace (later)
- · Retain computation-centric view
- · Data access and communication is part of orchestration

- 25 - — — CS 418 ·

High-level Goals

High performance (speedup over sequential program)

Step	Architecture- Dependent?	Major Performance Goals
Decomposition	Mostly no	Expose enough concurrency but not too much
Assignment	Mostly no	Balance workload Reduce communication volume
Orchestration	Yes	Reduce noninherent communication via data locality Reduce communication and synchonization or as seen by the processor Reduce serialization at shared resources Schedule tasks to satisfy dependences early
Mapping	Yes	Put related processes on the same processor in necessary Exploit locality in network topology

But low resource usage and development effort

Implications for algorithm designers and architects

- · Algorithm designers: high-perf., low resource needs
- Architects: high-perf., low cost, reduced programming effort
 - e.g. gradually improving perf. with programming effort may be preferable to sudden threshold after large programming effort

- 26 - _____ CS 418

What Parallel Programs Look Like

- 27 - CS 495 S'02 =

Parallelization of An Example Program

Motivating problems all lead to large, complex programs

Examine simplified version of a piece of Ocean simulation

· Iterative equation solver

Illustrate parallel program in low-level parallel language

- · C-like pseudocode with simple extensions for parallelism
- · Expose basic comm. and synch. primitives that must be supported
- · State of most real parallel programming today

- 28 - _____ CS 418

Grid Solver Example

Expression for updating each interior point:

```
A[i,j] = 0.2 \times (A[i,j]+A[i,j-1]+A[i-1,j]+A[i,j+1]+A[i+1,j])
```

- · Simplified version of solver in Ocean simulation
- · Gauss-Seidel (near-neighbor) sweeps to convergence
 - interior n-by-n points of (n+2)-by-(n+2) updated in each sweep
 - updates done in-place in grid, and diff. from prev. value computed
 - accumulate partial diffs into global diff at end of every sweep
 - check if error has converged (to within a tolerance parameter)
 - if so, exit solver; if not, do another sweep

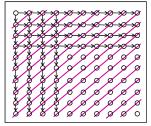

```
= - 29 - _____ CS 418 =
```

```
1. int n;
                                            /*size of matrix: (n + 2-by-n + 2) elements*/
2. float **A, diff = 0;
3. main()
4. begin
     read(n);
                                           /*read input parameter: matrix size*/
     A \leftarrow \text{malloc} (a 2-d array of size n + 2 by n + 2 doubles);
     initialize(A);
                                            /*initialize the matrix A somehow*/
     Solve (A);
                                            /*call the routine to solve equation*/
9. end main
10.procedure Solve (A)
                                            /*solve the equation system*/
11. float **A;
                                            /*A is an (n + 2)-by-(n + 2) array*/
12.begin
13. int i, j, done = 0;
14.
     float diff = 0, temp;
     while (!done) do
                                            /*outermost loop over sweeps*/
                                            /*initialize maximum difference to 0*/
16.
        diff = 0;
        for i \leftarrow 1 to n do
                                            /*sweep over nonborder points of grid*/
17.
18.
           for j \leftarrow 1 to n do
19.
              temp = A[i,j];
                                           /*save old value of element*/
20.
              A[i,j] \leftarrow 0.2 * (A[i,j] + A[i,j-1] + A[i-1,j] +
21.
                 A[i,j+1] + A[i+1,j]); /*compute average*/
22.
              diff += abs(A[i,j] - temp);
23.
           end for
        end for
25.
        if (diff/(n*n) < TOL) then done = 1;
     end while
27. end procedure
                                                             CS 495 5'02 =
= - 30 - =
```

Page 15

Decomposition

- ·Simple way to identify concurrency is to look at loop iterations
 - -dependence analysis; if not enough concurrency, then look further
- ·Not much concurrency here at this level (all loops sequential)
- ·Examine fundamental dependences, ignoring loop structure

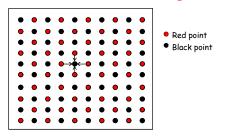

- · Concurrency O(n) along anti-diagonals, serialization O(n) along diag.
- · Retain loop structure, use pt-to-pt synch; Problem: too many synch ops.
- · Restructure loops, use global synch; imbalance and too much synch

- 31 - CS 418

Exploit Application Knowledge

· Reorder grid traversal: red-black ordering

- · Different ordering of updates: may converge quicker or slower
- · Red sweep and black sweep are each fully parallel
- · Global synch between them (conservative but convenient)
- Ocean uses red-black; we use simpler, asynchronous one to illustrate
 no red-black, simply ignore dependences within sweep
 - sequential order same as original, parallel program *nondeterministic*

- 32 - _____ CS 418

Decomposition Only

```
15. while (!done) do
                                    /*a sequential loop*/
     diff = 0;
16.
17.
      for_all i \leftarrow 1 to n do
                                    /*a parallel loop nest*/
18.
       for_all j \leftarrow 1 to n do
         temp = A[i,j];
19.
          A[i,j] \leftarrow 0.2 * (A[i,j] + A[i,j-1] + A[i-1,j] +
20.
            A[i,j+1] + A[i+1,j]);
21.
22.
          diff += abs(A[i,j] - temp);
23.
        end for all
24. end for_all
25.
    if (diff/(n*n) < TOL) then done = 1;
26. end while
```

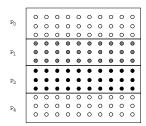

- · Decomposition into elements: degree of concurrency n²
- · To decompose into rows, make line 18 loop sequential; degree n
- for_all leaves assignment to the system
 - but implicit global synch, at end of for_all loop

= CS 418 = = - 33 - =

Assignment

·Static assignments (given decomposition into rows)

- -block assignment of rows: Row i is assigned to process $\lfloor p \rfloor$
- -cyclic assignment of rows: process i is assigned rows i, i+p, and so on

- · Dynamic assignment
 - get a row index, work on the row, get a new row, and so on
- · Static assignment into rows reduces concurrency (from n to p)
 - block assign, reduces communication by keeping adjacent rows together
- · Let's dig into orchestration under three programming models

= - 34 - =

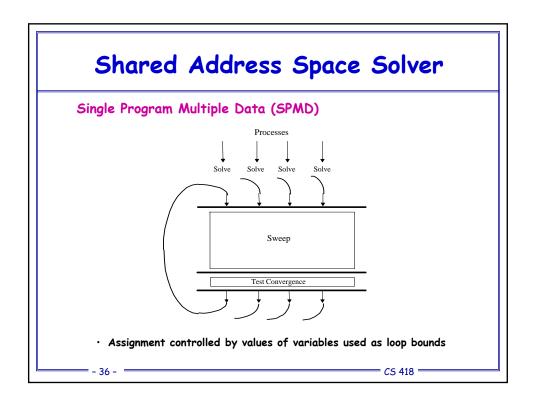

```
Data Parallel Solver
                                                                    /*grid size (n + 2-by-n + 2) and number of processes*/

    int n, nprocs;
    float **A, diff = 0;

       main()
4. begin

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   CS 495 5'02
```

Notes on SAS Program

- · SPMD: not lockstep or even necessarily same instructions
- · Assignment controlled by values of variables used as loop bounds
 - unique pid per process, used to control assignment
- · "Done" condition evaluated redundantly by all
- · Code that does the update identical to sequential program
 - each process has private mydiff variable
- · Most interesting special operations are for synchronization
 - accumulations into shared diff have to be mutually exclusive
 - why the need for all the barriers?

= - 38 - _____ CS 418

Need for Mutual Exclusion

· Code each process executes:

load the value of diff into register r1 add the register r2 to register r1 store the value of register r1 into diff

· A possible interleaving:

· Need the sets of operations to be atomic (mutually exclusive)

= - 39 - _____ CS 418 =

Mutual Exclusion

Provided by LOCK-UNLOCK around critical section

- · Set of operations we want to execute atomically
- · Implementation of LOCK/UNLOCK must guarantee mutual excl.

Can lead to significant serialization if contended

- · Especially since expect non-local accesses in critical section
- · Another reason to use private mydiff for partial accumulation

- 40 - CS 418

Global Event Synchronization

BARRIER(nprocs): wait here till nprocs processes get here

- · Built using lower level primitives
- · Global sum example: wait for all to accumulate before using sum
- · Often used to separate phases of computation

Process P_1Process P_2Process P_nprocsset up eqn systemset up eqn systemset up eqn system

Barrier (name, nprocs)

Barrier (name, nprocs)

Solve eqn system

Barrier (name, nprocs)

Barrier (name, nprocs) solve eqn system Barrier (name, nprocs) apply results

rrier (name, nprocs)

Barrier (name, nprocs)

 $\boldsymbol{\cdot}$ Conservative form of preserving dependences, but easy to use

WAIT_FOR_END (nprocs-1)

= - 41 - _____ CS 418 =

Pt-to-pt Event Synch (Not Used Here)

One process notifies another of an event so it can proceed

- · Common example: producer-consumer (bounded buffer)
- · Concurrent programming on uniprocessor: semaphores
- Shared address space parallel programs: semaphores, or use ordinary variables as flags

P₁
P₂
A = 1;
b: flag = 1;
a: while (flag is 0) do nothing;
print A;

·Busy-waiting or spinning

- 42 - _____ CS 418

Group Event Synchronization

Subset of processes involved

- · Can use flags or barriers (involving only the subset)
- · Concept of producers and consumers

Major types:

- · Single-producer, multiple-consumer
- · Multiple-producer, single-consumer

- 43 - CS 418 :

Message Passing Grid Solver

- · Cannot declare A to be shared array any more
- · Need to compose it logically from per-process private arrays
 - usually allocated in accordance with the assignment of work
 - process assigned a set of rows allocates them locally
- · Transfers of entire rows between traversals
- · Structurally similar to SAS (e.g. SPMD), but orchestration different
 - data structures and data access/naming
 - communication
 - synchronization

```
1. int pid, n, b; //process is, marrix dimension and number of processors to be used?/
2. float **syx}; processors to be used?/
3. main()
4. begin
5. read(n); read(nproce); //read input matrix size and number of processes./
58. CREATE (nproce=1, 50.1vs); //main process becomes a worker ton?/
80. MAIT FOR REMD (nproce=1); //wait for all child processes created to terminate?/
9. end main
10. procedure Solve()
11. begin
11. int i,j, pid, n' = n/nproce, done = 0;
14. float temp, tempdiff, mydiff = 0; //private variables*/
6. myA ← mallocia 2-d array of misse (float); pid=1, pid=1,
```

Notes on Message Passing Program

- · Use of ghost rows
- · Receive does not transfer data, send does
 - unlike SAS which is usually receiver-initiated (load fetches data)
- · Communication done at beginning of iteration, so no asynchrony
- · Communication in whole rows, not element at a time
- · Core similar, but indices/bounds in local rather than global space
- · Synchronization through sends and receives
 - Update of global diff and event synch for done condition
 - Could implement locks and barriers with messages
- · Can use REDUCE and BROADCAST library calls to simplify code

```
/*communicate local diff values and determine if done, using reduction and broadcast*/
25b. REDUCE(0,mydiff,sizeof(float),ADD);
25c. if (pid == 0) then
25i. if (mydiff/(n*n) < TOL) then done = 1;
25k. endif
25m. BROADCAST(0,done,sizeof(int),DONE);
```

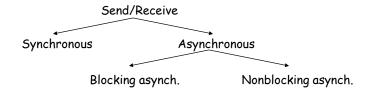

= - 46 - _____ CS 410

Send and Receive Alternatives

Can extend functionality: stride, scatter-gather, groups

Semantic flavors: based on when control is returned

Affect when data structures or buffers can be reused at either end

- · Affect event synch (mutual excl. by fiat: only one process touches data)
- · Affect ease of programming and performance

Synchronous messages provide built-in synch. through match

· Separate event synchronization needed with asynch. messages

With synch. messages, our code is deadlocked. Fix?

- 47 - CS 418 =

Orchestration: Summary

Shared address space

- · Shared and private data explicitly separate
- · Communication implicit in access patterns
- · No correctness need for data distribution
- · Synchronization via atomic operations on shared data
- · Synchronization explicit and distinct from data communication

Message passing

- · Data distribution among local address spaces needed
- · No explicit shared structures (implicit in comm. patterns)
- · Communication is explicit
- · Synchronization implicit in communication (at least in synch. case)
 - mutual exclusion by fiat

· 48 - CS 418

Correctness in Grid Solver Program

Decomposition and Assignment similar in SAS and message-passing Orchestration is different

· Data structures, data access/naming, communication, synchronization

	<u>SAS</u>	Msg-Passing
Explicit global data structure?	Yes	No
Assignment independent of data layout?	Yes	No
Communication	Implicit	Explicit
Synchronization	Explicit	Implicit
Explicit replication of border rows?	No	Yes

Requirements for performance are another story ...
