11-755/18-797 Machine Learning for Signal Processing

Fundamentals of Linear Algebra

Class 2-3. 1 Sep 2011

Instructor: Bhiksha Raj

Administrivia

- Registration: Anyone on waitlist still?
- Homework 1: Will be handed out with class 3.
  - Linear algebra

Overview

- Vectors and matrices
- Basic vector/matrix operations
- Vector products
- Matrix products
- Various matrix types
- Matrix inversion
- Matrix interpretation
- Eigenanalysis
- Singular value decomposition

Book

- Fundamentals of Linear Algebra, Gilbert Strang
- Important to be very comfortable with linear algebra
  - Appears repeatedly in the form of Eigen analysis, SVD, Factor analysis
  - Appears through various properties of matrices that are used in machine learning, particularly when applied to images and sound
- Today's lecture: Definitions
  - Very small subset of all that's used
  - Important subset, intended to help you recollect

Incentive to use linear algebra

- Pretty notation!

$$\mathbf{x}^T \cdot \mathbf{A} \cdot \mathbf{y} \longleftrightarrow \sum_j y_j \sum_i x_i a_{ij}$$

- Easier intuition
  - *Really convenient geometric interpretations*
  - Operations easy to describe verbally
- Easy code translation!

```
for i=1:n
  for j=1:m
    c(i)=c(i)+y(j)*x(i)*a(i,j)
  end
end
```

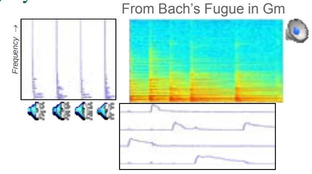
$\longleftrightarrow$

```
C=x*A*y
```

And other things you can do

Rotation + Projection + Scaling

From Bach's Fugue in Gm



Decomposition (NMF)

- Manipulate Images
- Manipulate Sounds

Scalars, vectors, matrices, …

- A *scalar* a is a number
  - a = 2, a = 3.14, a = -1000, etc.
- A *vector* **a** is a linear arrangement of a collection of scalars

$$\mathbf{a} = \begin{bmatrix} 1 & 2 & 3 \end{bmatrix}, \quad \mathbf{a} = \begin{bmatrix} 3.14 \\ -32 \end{bmatrix}$$

- A *matrix* **A** is a rectangular arrangement of a collection of vectors

$$\mathbf{A} = \begin{bmatrix} 3.12 & -10 \\ 10.0 & 2 \end{bmatrix}$$

- MATLAB syntax: `a=[1 2 3], A=[1 2;3 4]`

Vector/Matrix types and shapes

- Vectors are either column or row vectors

$$\mathbf{c} = \begin{bmatrix} a \\ b \\ c \end{bmatrix}, \quad \mathbf{r} = \begin{bmatrix} a & b & c \end{bmatrix} \quad \mathbf{s} = [\ \ ]$$

  - A sound can be a vector, a series of daily temperatures can be a vector, etc …
- Matrices can be square or rectangular

$$\mathbf{S} = \begin{bmatrix} a & b \\ c & d \end{bmatrix}, \quad \mathbf{R} = \begin{bmatrix} a & b & c \\ d & e & f \end{bmatrix}, \quad \mathbf{M} =$$

  - Images can be a matrix, collections of sounds can be a matrix, etc …

Dimensions of a matrix

- The matrix size is specified by the number of rows and columns

$$\mathbf{c} = \begin{bmatrix} a \\ b \\ c \end{bmatrix}, \quad \mathbf{r} = \begin{bmatrix} a & b & c \end{bmatrix}$$

  - c = 3x1 matrix: 3 rows and 1 column
  - r = 1x3 matrix: 1 row and 3 columns

$$\mathbf{S} = \begin{bmatrix} a & b \\ c & d \end{bmatrix}, \quad \mathbf{R} = \begin{bmatrix} a & b & c \\ d & e & f \end{bmatrix}$$

  - S = 2 x 2 matrix
  - R = 2 x 3 matrix
  - Pacman = 321 x 399 matrix

Representing an image as a matrix

Y	1	1	.	2	.	2	2	.	2	.	10
X	1	2	.	1	.	5	6	.	10	.	10
v	1	1	.	1	.	0	0	.	1	.	1

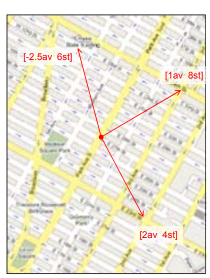
[1 . 1 1 . 0 0 0 . . 1]

Values only; X and Y are implicit

- 3 pacmen
- A 321x399 matrix
  - Row and Column = position
- A 3x128079 matrix
  - Triples of x,y and value
- A 1x128079 vector
  - "Unraveling" the matrix
- Note: All of these can be recast as the matrix that forms the image
  - Representations 2 and 4 are equivalent
    - The position is not represented

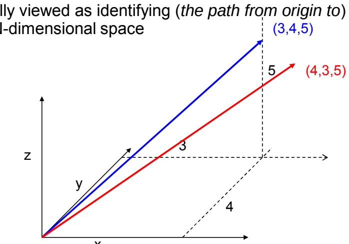
Example of a vector

- Vectors usually hold sets of numerical attributes
  - X, Y, value
    - [1, 2, 0]
  - Earnings, losses, suicides
    - [$0 $1.000.000 3]
  - Etc …
- Consider a "relative Manhattan" vector
  - Provides a relative position by giving a number of avenues and streets to cross, e.g. [3av 33st]

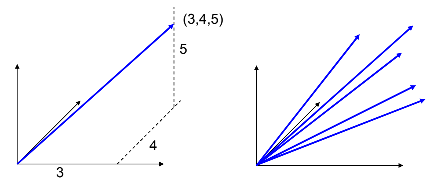


Vectors

- Ordered collection of numbers
  - Examples: [3 4 5], [a b c d], ..
  - [3 4 5] != [4 3 5] → **Order is important**
- Typically viewed as identifying (*the path from origin to*) a location in an N-dimensional space



Vectors vs. Matrices



- A vector is a geometric notation for how to get from (0,0) to some location in the space
- A matrix is simply a collection of destinations!
  - Properties of matrices are *average* properties of the traveller's path to these destinations

Basic arithmetic operations

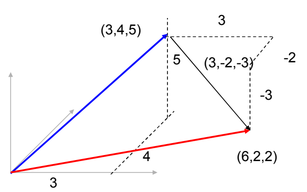
- Addition and subtraction
  - Element-wise operations

$$\mathbf{a}+\mathbf{b}=\begin{bmatrix}a_1\\a_2\\a_3\end{bmatrix}+\begin{bmatrix}b_1\\b_2\\b_3\end{bmatrix}=\begin{bmatrix}a_1+b_1\\a_2+b_2\\a_3+b_3\end{bmatrix}\quad \mathbf{a}-\mathbf{b}=\begin{bmatrix}a_1\\a_2\\a_3\end{bmatrix}-\begin{bmatrix}b_1\\b_2\\b_3\end{bmatrix}=\begin{bmatrix}a_1-b_1\\a_2-b_2\\a_3-b_3\end{bmatrix}$$

$$\mathbf{A}+\mathbf{B}=\begin{bmatrix}a_{11}&a_{12}\\a_{21}&a_{22}\end{bmatrix}+\begin{bmatrix}b_{11}&b_{12}\\b_{21}&b_{22}\end{bmatrix}=\begin{bmatrix}a_{11}+b_{11}&a_{12}+b_{12}\\a_{21}+b_{21}&a_{22}+b_{22}\end{bmatrix}$$

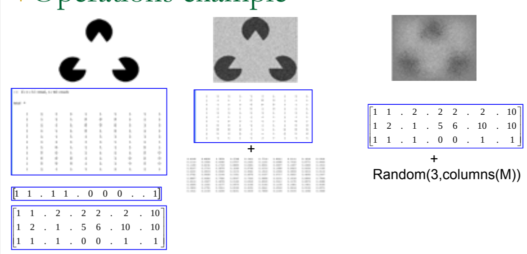
- MATLAB syntax: `a+b` and `a-b`

Vector Operations



- Operations tell us how to get from ({0}) to the result of the vector operations
  - (3,4,5) + (3,-2,-3) = (6,2,2)

Operations example



- Adding random values to different representations of the image

Vector norm

- Measure of how big a vector is:
  - Notated as $\|\mathbf{x}\|$

$$\left\|\begin{bmatrix}a & b & \ldots\end{bmatrix}\right\|=\sqrt{a^2+b^2+\ldots^2}$$

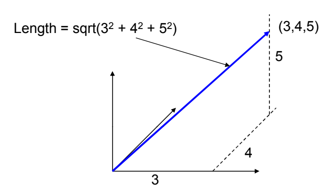
- In Manhattan vectors a measure of distance

$$\left\|\begin{bmatrix}-2 & 17\end{bmatrix}\right\|=17.11$$

$$\left\|\begin{bmatrix}-6 & 10\end{bmatrix}\right\|=11.66$$

- MATLAB syntax:
  `norm(x)`

Vector Norm



- Geometrically the shortest distance to travel from the origin to the destination
  - As the crow flies
  - Assuming Euclidean Geometry

Transposition

- A transposed row vector becomes a column (and vice versa)

$$\mathbf{x} = \begin{bmatrix} a \\ b \\ c \end{bmatrix}, \ \mathbf{x}^T = \begin{bmatrix} a & b & c \end{bmatrix} \qquad \mathbf{y} = \begin{bmatrix} a & b & c \end{bmatrix}, \ \mathbf{y}^T = \begin{bmatrix} a \\ b \\ c \end{bmatrix}$$

- A transposed matrix gets all its row (or column) vectors transposed in order

$$\mathbf{X} = \begin{bmatrix} a & b & c \\ d & e & f \end{bmatrix}, \ \mathbf{X}^T = \begin{bmatrix} a & d \\ b & e \\ c & f \end{bmatrix}$$

$\mathbf{M} =$  , $\mathbf{M}^T =$ 

- MATLAB syntax: `a'`

Vector multiplication

- Multiplication is not element-wise!
- Dot product, or inner product
  - Vectors must have the same number of elements
  - Row vector times column vector = scalar

$$\begin{bmatrix} a & b & c \end{bmatrix} \cdot \begin{bmatrix} d \\ e \\ f \end{bmatrix} = a \cdot d + b \cdot e + c \cdot f$$

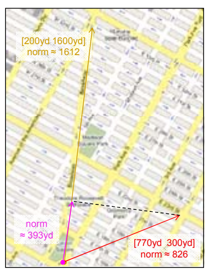
- Cross product, outer product or vector direct product
  - Column vector times row vector = matrix

$$\begin{bmatrix} a \\ b \\ c \end{bmatrix} \cdot \begin{bmatrix} d & e & f \end{bmatrix} = \begin{bmatrix} a \cdot d & a \cdot e & a \cdot f \\ b \cdot d & b \cdot e & b \cdot f \\ c \cdot d & c \cdot e & c \cdot f \end{bmatrix}$$

- MATLAB syntax: `a*b`

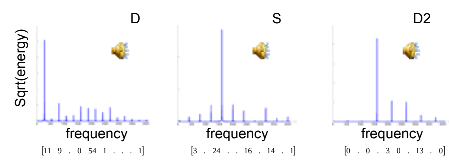
Vector *dot product* in Manhattan

- Multiplying the "yard" vectors
  - Instead of avenue/street we'll use yards
  - a = [200 1600], b = [770 300]
- The dot product of the two vectors relates to the length of a *projection*
  - How much of the first vector have we covered by following the second one?
  - The answer comes back as a unit of the first vector so we divide by its length



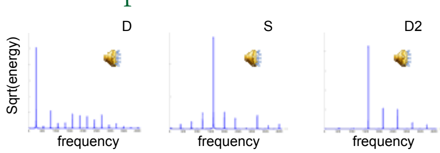
$$\frac{\mathbf{ab}^T}{\|\mathbf{a}\|} = \frac{\begin{bmatrix} 200 & 1600 \end{bmatrix} \cdot \begin{bmatrix} 770 \\ 300 \end{bmatrix}}{\left\|\begin{bmatrix} 200 & 1600 \end{bmatrix}\right\|} \approx 393\text{yd}$$

Vector dot product



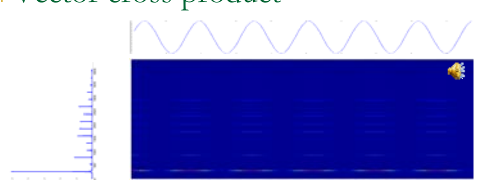
- Vectors are spectra
  - Energy at a discrete set of frequencies
  - Actually 1x4096
  - X axis is the *index* of the number in the vector
    - Represents frequency
  - Y axis is the value of the number in the vector
    - Represents magnitude

Vector dot product



- How much of D is also in S
  - How much can you fake a D by playing an S
  - D.S / |D||S| = 0.1
  - Not very much
- How much of D is in D2?
  - D.D2 / |D| /|D2| = 0.5
  - Not bad, you can fake it
- To do this, D, S, and D2 *must be the same size*

Vector cross product



- The column vector is the spectrum
- The row vector is an amplitude modulation
- The crossproduct is a spectrogram
  - Shows how the energy in each frequency varies with time
  - The pattern in each column is a scaled version of the spectrum
  - Each row is a scaled version of the modulation

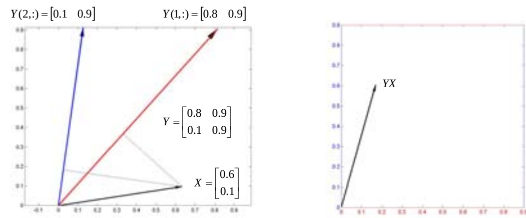
Matrix multiplication

- Generalization of vector multiplication
  - Dot product of each vector pair

$$\mathbf{A}\cdot\mathbf{B} = \begin{bmatrix} \leftarrow & \mathbf{a}_1 & \rightarrow \\ \leftarrow & \mathbf{a}_2 & \rightarrow \end{bmatrix} \cdot \begin{bmatrix} \uparrow & \uparrow \\ \mathbf{b}_1 & \mathbf{b}_2 \\ \downarrow & \downarrow \end{bmatrix} = \begin{bmatrix} \mathbf{a}_1\cdot\mathbf{b}_1 & \mathbf{a}_1\cdot\mathbf{b}_2 \\ \mathbf{a}_2\cdot\mathbf{b}_1 & \mathbf{a}_2\cdot\mathbf{b}_2 \end{bmatrix}$$

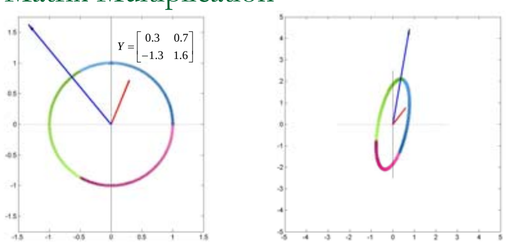
  - Dimensions must match!!
    - Columns of first matrix = rows of second
    - Result inherits the number of rows from the first matrix and the number of columns from the second matrix
- MATLAB syntax: `a*b`

Multiplying a Vector by a Matrix



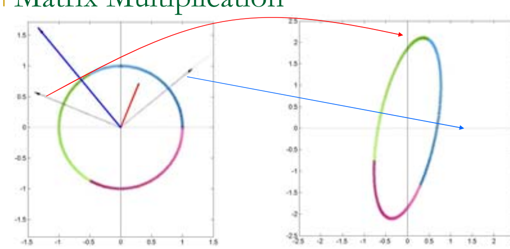
- Multiplication of a vector X by a matrix Y expresses the vector X in terms of projections of X on the row vectors of the matrix Y
  - It scales and rotates the vector
  - Alternately viewed, it scales and rotates the space – the underlying plane

Matrix Multiplication



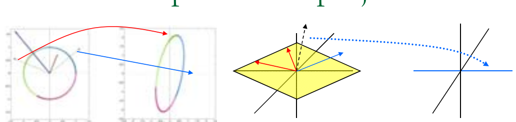
- The matrix rotates and scales the space
  - Including its own vectors

Matrix Multiplication



- The *normals* to the row vectors in the matrix become the new axes
  - X axis = normal to the *second* row vector
    - Scaled by the inverse of the length of the *first* row vector

Matrix Multiplication is projection



- The k-th axis corresponds to the normal to the hyperplane represented by the 1..k-1,k+1..N-th row vectors in the matrix
  - Any set of K-1 vectors represent a hyperplane of dimension K-1 or less
- The distance along the new axis equals the length of the projection on the k-th row vector
  - Expressed in inverse-lengths of the vector

Matrix Multiplication: Column space

$$\begin{bmatrix} a & b & c \\ d & e & f \end{bmatrix}\begin{bmatrix} x \\ y \\ z \end{bmatrix} = x\begin{bmatrix} a \\ d \end{bmatrix} + y\begin{bmatrix} b \\ e \end{bmatrix} + z\begin{bmatrix} c \\ f \end{bmatrix}$$

- So much for spaces .. what does multiplying a matrix by a vector really do?
- It *mixes* the column vectors of the matrix using the numbers in the vector
- The *column space* of the Matrix is the complete set of all vectors that can be formed by mixing its columns

Matrix Multiplication: Row space

$$\begin{bmatrix} x & y \end{bmatrix}\begin{bmatrix} a & b & c \\ d & e & f \end{bmatrix} = x\begin{bmatrix} a & b & c \end{bmatrix} + y\begin{bmatrix} d & e & f \end{bmatrix}$$

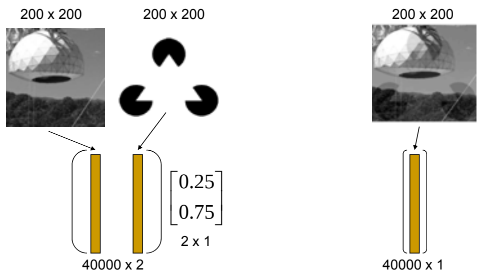
- Left multiplication mixes the *row vectors* of the matrix.
- The *row space* of the Matrix is the complete set of all vectors that can be formed by mixing its rows

Matrix multiplication: Mixing vectors

$$\overset{X}{\begin{bmatrix} 1 & 3 & 0 \\ . & . & 0 \\ 9 & 24 & . \\ . & . & 1 \end{bmatrix}} \overset{Y}{\begin{bmatrix} 1 \\ 2 \\ 1 \end{bmatrix}} = \begin{bmatrix} 7 \\ . \\ . \\ 2 \end{bmatrix}$$

- A physical example
  - The three column vectors of the matrix X are the spectra of three notes
  - The multiplying column vector Y is just a mixing vector
  - The result is a sound that is the mixture of the three notes

Matrix multiplication: Mixing vectors



$$\begin{bmatrix} 0.25 \\ 0.75 \end{bmatrix}$$

2 x 1

- Mixing two images
  - The images are arranged as columns
    - position value not included
  - The result of the multiplication is rearranged as an image

Matrix multiplication: another view

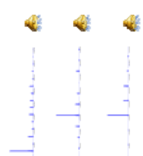
$$\mathbf{A}\cdot\mathbf{B} = \begin{bmatrix} a_{11} & . & . & a_{1N} \\ a_{21} & . & . & a_{2N} \\ . & . & . & . \\ a_{M1} & . & . & a_{MN} \end{bmatrix} \cdot \begin{bmatrix} b_{11} & . & b_{NK} \\ . & . & . \\ b_{N1} & . & b_{NK} \end{bmatrix} = \begin{bmatrix} \sum_k a_{1k}b_{k1} & . & \sum_k a_{1k}b_{kK} \\ . & . & . \\ \sum_k a_{Mk}b_{k1} & . & \sum_k a_{Mk}b_{kK} \end{bmatrix}$$

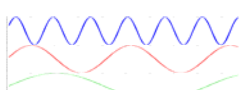
- What does this mean?

$$\begin{bmatrix} a_{11} & . & . & a_{1N} \\ a_{21} & . & . & a_{2N} \\ . & . & . & . \\ a_{M1} & . & . & a_{MN} \end{bmatrix} \cdot \begin{bmatrix} b_{11} & . & b_{NK} \\ . & . & . \\ b_{N1} & . & b_{NK} \end{bmatrix} = \begin{bmatrix} a_{11} \\ . \\ . \\ a_{M1} \end{bmatrix}\begin{bmatrix} b_{11} & . & b_{1K} \end{bmatrix} + \begin{bmatrix} a_{12} \\ . \\ . \\ a_{M2} \end{bmatrix}\begin{bmatrix} b_{21} & . & b_{2K} \end{bmatrix} + \ldots + \begin{bmatrix} a_{1N} \\ . \\ . \\ a_{MN} \end{bmatrix}\begin{bmatrix} b_{N1} & . & b_{NK} \end{bmatrix}$$

- The outer product of the first column of A and the first row of B + outer product of the second column of A and the second row of B + ….

Why is that useful?

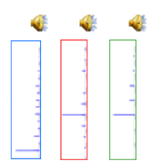


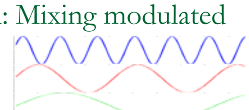


$$\underset{X}{\begin{bmatrix} 1 & 3 & 0 \\ . & . & 0 \\ 9 & 24 & . \\ . & . & 1 \end{bmatrix}} \quad \underset{Y}{\begin{bmatrix} 0 & 0.5 & 0.75 & 1 & 0.75 & 0.5 & 0 & . & . & . & . & . \\ 1 & 0.9 & 0.7 & 0.5 & 0 & 0.5 & . & . & . & . & . & . \\ 0.5 & 0.6 & 0.7 & 0.8 & 0.9 & 0.95 & 1 & . & . & . & . & . \end{bmatrix}}$$

- Sounds: Three notes modulated independently

Matrix multiplication: Mixing modulated spectra

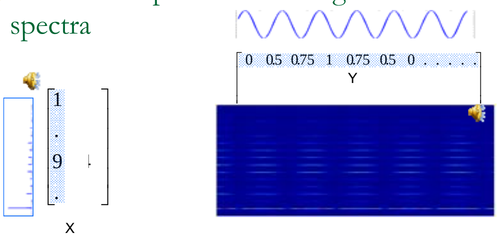




$$\underset{X}{\begin{bmatrix} 1 & 3 & 0 \\ . & . & 0 \\ 9 & 24 & . \\ . & . & 1 \end{bmatrix}} \quad \underset{Y}{\begin{bmatrix} 0 & 0.5 & 0.75 & 1 & 0.75 & 0.5 & 0 & . & . & . & . & . \\ 1 & 0.9 & 0.7 & 0.5 & 0 & 0.5 & . & . & . & . & . & . \\ 0.5 & 0.6 & 0.7 & 0.8 & 0.9 & 0.95 & 1 & . & . & . & . & . \end{bmatrix}}$$

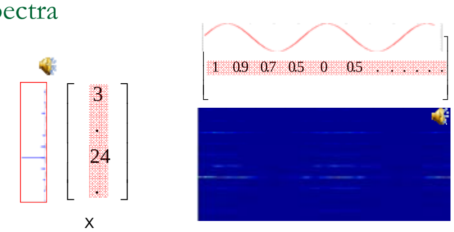
- Sounds: Three notes modulated independently

Matrix multiplication: Mixing modulated spectra



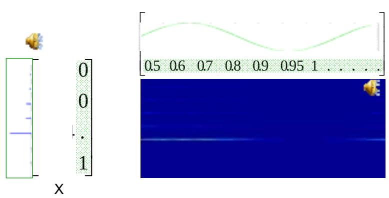
- Sounds: Three notes modulated independently

Matrix multiplication: Mixing modulated spectra



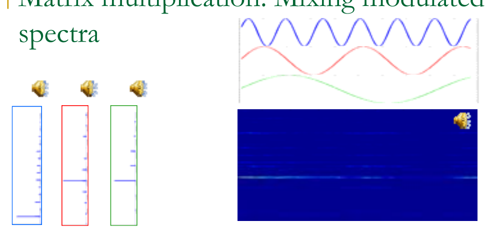
- Sounds: Three notes modulated independently

Matrix multiplication: Mixing modulated spectra



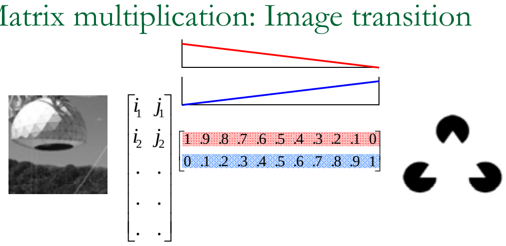
- Sounds: Three notes modulated independently

Matrix multiplication: Mixing modulated spectra



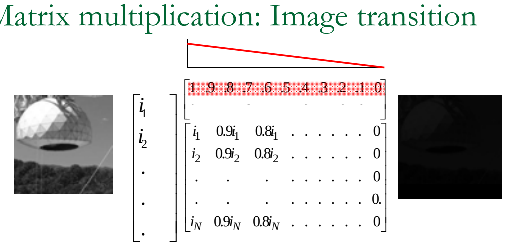
- Sounds: Three notes modulated independently

Matrix multiplication: Image transition



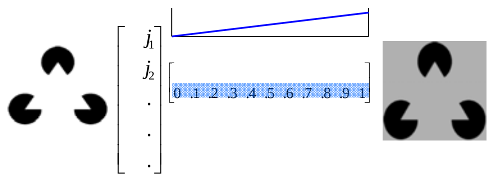
- Image1 fades out linearly
- Image 2 fades in linearly

Matrix multiplication: Image transition



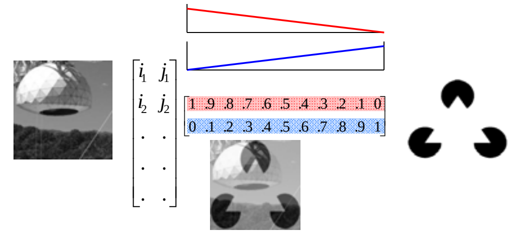
- Each column is one image
  - The columns represent a sequence of images of decreasing intensity
- Image1 fades out linearly

Matrix multiplication: Image transition



- Image 2 fades in linearly

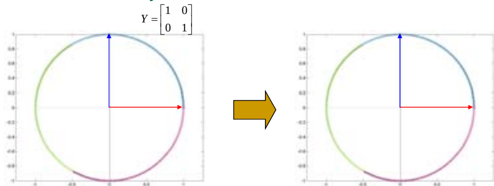
Matrix multiplication: Image transition



- Image1 fades out linearly
- Image 2 fades in linearly

The Identity Matrix

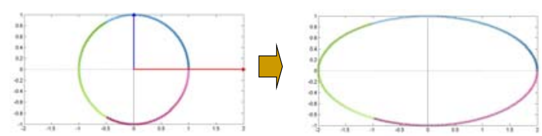
$$Y = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$



- An identity matrix is a square matrix where
  - All diagonal elements are 1.0
  - All off-diagonal elements are 0.0
- Multiplication by an identity matrix does not change vectors

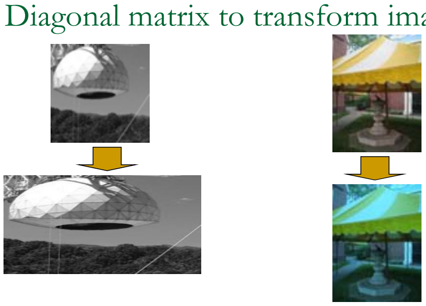
Diagonal Matrix

$$Y = \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}$$



- All off-diagonal elements are zero
- Diagonal elements are non-zero
- Scales the axes
  - May flip axes

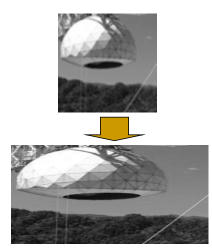
Diagonal matrix to transform images



- How?

Stretching

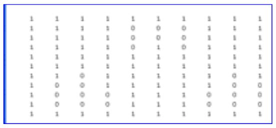
$$\begin{bmatrix} 2 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 1 & . & 2 & . & 2 & 2 & . & 2 & . & 10 \\ 1 & 2 & . & 1 & . & 5 & 6 & . & 10 & . & 10 \\ 1 & 1 & . & 1 & . & 0 & 0 & . & 1 & . & 1 \end{bmatrix}$$

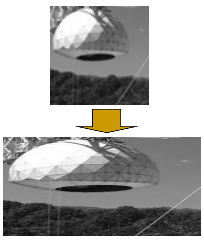


- Location-based representation
- Scaling matrix – only scales the X axis
  - The Y axis and pixel value are scaled by identity
- Not a good way of scaling.

Stretching

D =



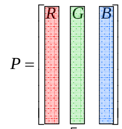


$$A = \begin{bmatrix} 1 & .5 & 0 & 0 & . \\ 0 & .5 & 1 & .5 & . \\ 0 & 0 & 0 & .5 & . \\ 0 & 0 & 0 & 0 & . \\ . & . & . & . & . \end{bmatrix} (N\text{x}2N)$$

$$\text{Newpic} = EA$$

- Better way

Modifying color

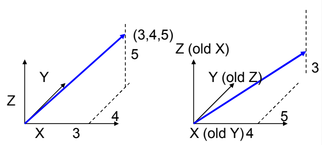


$$Newpic = P \begin{bmatrix} 1 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

- Scale only Green

Permutation Matrix

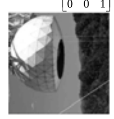
$$\begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \end{bmatrix} = \begin{bmatrix} y \\ z \\ x \end{bmatrix}$$



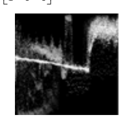
- A permutation matrix simply rearranges the axes
  - The row entries are axis vectors in a different order
  - The result is a combination of rotations and reflections
- The permutation matrix effectively *permutes* the arrangement of the elements in a vector

Permutation Matrix

$$P = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$



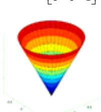
$$P = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}$$

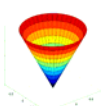


- Reflections and 90 degree rotations of images and objects

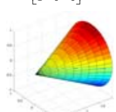
Permutation Matrix

$$P = \begin{bmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$





$$P = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}$$



$$\begin{bmatrix} x_1 & x_2 & . & . & x_N \\ y_1 & y_2 & . & . & y_N \\ z_1 & z_2 & . & . & z_N \end{bmatrix}$$

- Reflections and 90 degree rotations of images and objects
  - Object represented as a matrix of 3-Dimensional "position" vectors
  - Positions identify each point on the surface

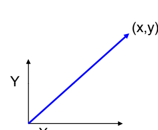
Rotation Matrix

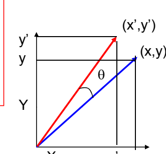
$$x' = x\cos\theta - y\sin\theta$$
$$y' = x\sin\theta + y\cos\theta$$

$$\mathbf{R}_\theta = \begin{bmatrix} \cos\theta & -\sin\theta \\ \sin\theta & \cos\theta \end{bmatrix}$$

$$X = \begin{bmatrix} x \\ y \end{bmatrix} \quad X_{new} = \begin{bmatrix} x' \\ y' \end{bmatrix}$$

$$R_\theta X = X_{new}$$





- A rotation matrix *rotates* the vector by some angle θ
- Alternately viewed, it rotates the axes
  - The new axes are at an angle θ to the old one

Rotating a picture

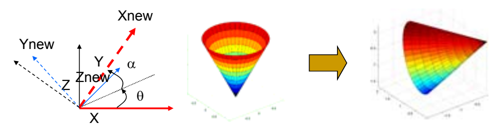
$$R = \begin{bmatrix} \cos 45 & -\sin 45 & 0 \\ \sin 45 & \cos 45 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

$$\begin{bmatrix} 1 & 1 & . & 2 & . & 2 & 2 & . & 2 & . & . \\ 1 & 2 & . & 1 & . & 5 & 6 & . & 10 & . & . \\ 1 & 1 & . & 1 & . & 0 & 0 & . & 1 & . & 1 \end{bmatrix}$$

$$\begin{bmatrix} 0 & -\sqrt{2} & . & \sqrt{2} & . & -3\sqrt{2} & -4\sqrt{2} & . & -8\sqrt{2} & . & . \\ \sqrt{2} & 3\sqrt{2} & . & 3\sqrt{2} & . & 7\sqrt{2} & 8\sqrt{2} & . & 12\sqrt{2} & . & . \\ 1 & 1 & . & 1 & . & 0 & 0 & . & 1 & . & 1 \end{bmatrix}$$

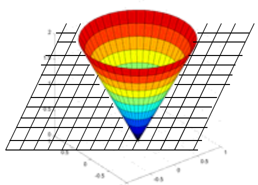
- Note the representation: 3-row matrix
  - Rotation only applies on the “coordinate” rows
  - The value does not change
  - Why is pacman grainy?

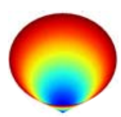
3-D Rotation



- 2 degrees of freedom
  - 2 separate angles
- What will the rotation matrix be?

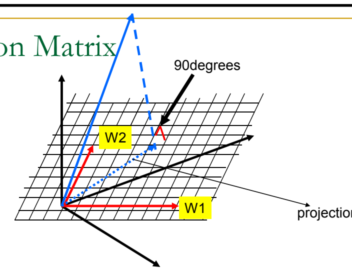
Projections





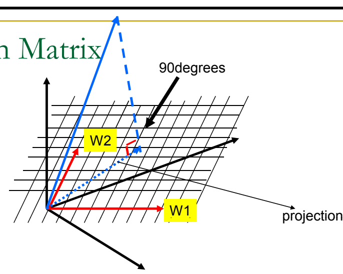
- What would we see if the cone to the left were transparent if we looked at it along the normal to the plane
  - The plane goes through the origin
  - Answer: the figure to the right
- How do we get this? Projection

Projection Matrix



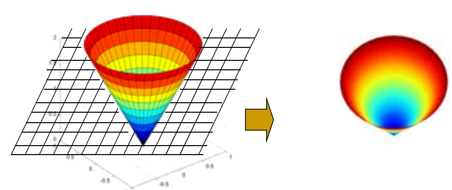
- Consider any plane specified by a set of vectors W_1, W_2..
  - Or matrix [W_1 W_2 ..]
  - Any vector can be projected onto this plane
  - The matrix A that rotates and scales the vector so that it becomes its projection is a projection matrix

Projection Matrix



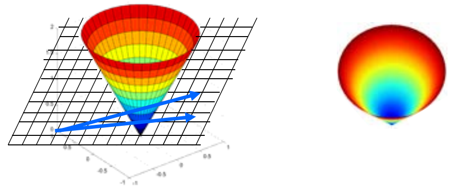
- Given a set of vectors W1, W2, which form a matrix W = [W1 W2..]
- The projection matrix that transforms any vector X to its projection on the plane is
  - $P = W (W^T W)^{-1} W^T$
    - We will visit matrix inversion shortly
- Magic – any set of vectors from the same plane that are expressed as a matrix will give you the same projection matrix
  - $P = V (V^T V)^{-1} V^T$

Projections



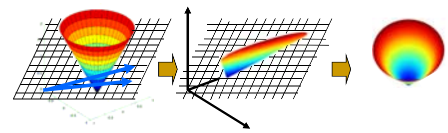
- HOW?

Projections



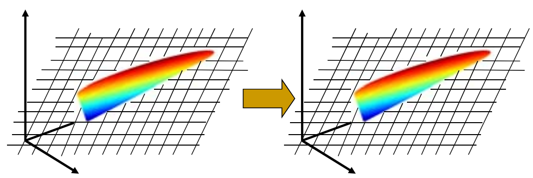
- Draw any two vectors W1 and W2 that lie on the plane
  - ***ANY two*** **so long as they have different angles**
- Compose a matrix W = [W1 W2]
- Compose the projection matrix $P = W (W^TW)^{-1} W^T$
- Multiply every point on the cone by P to get its projection
- View it ☺
  - I'm missing a step here – what is it?

Projections



- The projection actually projects it onto the plane, but you're still seeing the plane in 3D
  - The result of the projection is a 3-D vector
  - $P = W (W^TW)^{-1} W^T = 3x3$, P*Vector = 3x1
  - The image must be rotated till the plane is in the plane of the paper
    - The Z axis in this case will always be zero and can be ignored
    - How will you rotate it? (remember you know W1 and W2)

Projection matrix properties



- The projection of any vector that is already on the plane is the vector itself
  - Px = x if x is on the plane
  - If the object is already on the plane, there is no further projection to be performed
- The projection of a projection is the projection
  - P (Px) = Px
  - That is because Px is already on the plane
- Projection matrices are *idempotent*
  - $P^2 = P$
    - Follows from the above
