Problem 1

Determine asymptotic bounds for each of the following recurrences.

(a) $T(n) = 3 \cdot T(n/27) + n$.

We use the master method; since $3 < 27$, we conclude that $T(n) = \Theta(n)$.

(b) $T(n) = 3 \cdot T(n/27) + \sqrt[3]{n}$.

$$\begin{aligned}
 T(n) &= \sqrt[3]{n} + 3 \cdot T\left(\frac{n}{27}\right) \\
 &= \sqrt[3]{n} + 3 \cdot \left(\sqrt[3]{\frac{n}{27}} + 3 \cdot T\left(\frac{n}{27^2}\right) \right) \\
 &= \sqrt[3]{n} + 3 \cdot \sqrt[3]{\frac{n}{27}} + 3^2 \cdot T\left(\frac{n}{27^2}\right) \\
 &= \sqrt[3]{n} + 3 \cdot \sqrt[3]{\frac{n}{27}} + 3^2 \cdot \left(\sqrt[3]{\frac{n}{27^2}} + 3 \cdot T\left(\frac{n}{27^3}\right) \right) \\
 &= \sqrt[3]{n} + 3 \cdot \sqrt[3]{\frac{n}{27}} + 3^2 \cdot \sqrt[3]{\frac{n}{27^2}} + 3^3 \cdot T\left(\frac{n}{27^3}\right) \\
 &\quad \dots \\
 &= \sqrt[3]{n} + 3 \cdot \sqrt[3]{\frac{n}{27}} + 3^2 \cdot \sqrt[3]{\frac{n}{27^2}} + 3^3 \cdot \sqrt[3]{\frac{n}{27^3}} + 3^4 \cdot \sqrt[3]{\frac{n}{27^4}} + \dots + 3^{\log_{27} n} \cdot \sqrt[3]{\frac{n}{27^{\log_{27} n}}} \\
 &= \underbrace{\sqrt[3]{n} + \sqrt[3]{n} + \sqrt[3]{n} + \sqrt[3]{n} + \dots + \sqrt[3]{n}}_{\log_{27} n + 1} \\
 &= \sqrt[3]{n} \cdot (\log_{27} n + 1) \\
 &= \Theta(\sqrt[3]{n} \cdot \lg n).
 \end{aligned}$$

(c) $T(n) = T(n/6) + T(n/3) + T(n/2) + n$.

We use the iteration method, which leads to the following tree:

The summation gives a lower and upper bound for $T(n)$:

$$n \cdot (\log_6 n + 1) \leq T(n) \leq n \cdot (\log_2 n + 1),$$

which implies that $T(n) = \Theta(n \cdot \lg n)$.

(d) $T(n) = T(n - 1) + 1/2^n$.

$$\begin{aligned} T(n) &= T(n - 1) + \frac{1}{2^n} \\ &= T(n - 2) + \frac{1}{2^{n-1}} + \frac{1}{2^n} \\ &\quad \dots \\ &= \frac{1}{2^1} + \frac{1}{2^2} + \frac{1}{2^3} + \dots + \frac{1}{2^{n-1}} + \frac{1}{2^n} \\ &= 1 - \frac{1}{2^n} \\ &= \Theta(1). \end{aligned}$$

(e) $T(n) = 2 \cdot T(\sqrt{n}) + 1$.

We “unwind” the recurrence until reaching some constant value of n , say, until $n \leq 2$:

$$T(n) = \begin{cases} \Theta(1), & \text{if } n \leq 2 \\ 2 \cdot T(\sqrt{n}) + 1, & \text{if } n > 2 \end{cases}$$

For convenience, assume that $n = 2^{2^k}$, for some natural value k .

$$\begin{aligned}
T(2^{2^k}) &= 1 + 2 \cdot T(\sqrt{2^{2^k}}) \\
&= 1 + 2 \cdot T(2^{2^{k-1}}) \\
&= 1 + 2 \cdot \left(1 + 2 \cdot T(\sqrt{2^{2^{k-1}}})\right) \\
&= 1 + 2 + 4 \cdot T(2^{2^{k-2}}) \\
&= 1 + 2 + 4 \cdot \left(1 + 2 \cdot T(\sqrt{2^{2^{k-2}}})\right) \\
&= 1 + 2 + 4 + 8 \cdot T(2^{2^{k-3}}) \\
&\quad \dots \\
&= 1 + 2 + 4 + \dots + 2^{k-1} + T(2) \\
&= 2^k - 1 + \Theta(1) \\
&= \Theta(2^k).
\end{aligned}$$

Finally, we note that $k = \lg \lg n$, which means that $T(n) = \Theta(2^{\lg \lg n}) = \Theta(\lg n)$.

Problem 2

The standard analysis of `MERGE-SORT`(A, p, q) is based on the assumption that we pass $A[1..n]$ by a pointer. If a language does not allow passing an array by a pointer, we may have two other options; for each option, determine the running time of `MERGE-SORT`.

(a) Copy all elements of the array $A[1..n]$, which takes $\Theta(n)$ time.

Let n be the size of the array $A[1..n]$, and m be the size of the segment $A[p..q]$, sorted by the recursive call `MERGE-SORT`(A, p, q). The time of copying the array is $\Theta(n)$, and the time of the `MERGE` operation is $\Theta(m)$, which leads to the following recurrence:

$$T(m) = 2 \cdot T(m/2) + \Theta(n) + \Theta(m).$$

Since $m \leq n$, we conclude that

$$T(m) = 2 \cdot T(m/2) + \Theta(n) = 2 \cdot T(m/2) + c \cdot n,$$

and unwind this recurrence as follows:

$$\begin{aligned}
T(m) &= c \cdot n + 2 \cdot T(m/2) \\
&= c \cdot n + 2 \cdot c \cdot n + 2^2 \cdot T(m/4) \\
&= c \cdot n + 2 \cdot c \cdot n + 2^2 \cdot c \cdot n + 2^3 \cdot T(m/8) \\
&\quad \dots \\
&= c \cdot n + 2 \cdot c \cdot n + 2^2 \cdot c \cdot n + \dots + 2^{\lg m - 1} \cdot c \cdot n + 2^{\lg m} \cdot c \cdot n \\
&= (2^{\lg m + 1} - 1) \cdot c \cdot n \\
&= (2 \cdot m - 1) \cdot c \cdot n \\
&= \Theta(m \cdot n).
\end{aligned}$$

Thus, the running time of $\text{MERGE-SORT}(A, p, q)$ is $\Theta(m \cdot n)$, where m is the size of the segment $A[p..q]$. The top-level call to the sorting algorithm is $\text{MERGE-SORT}(A, 1, n)$; for this call, we have $m = n$, which means that the time complexity is

$$T(n) = \Theta(n^2).$$

(b) Copy the elements of the segment $A[p..q]$, which takes $\Theta(q - p + 1)$ time.

The complexity of copying the segment is $\Theta(m)$, which is the same as the time of the MERGE procedure; hence, copying does not affect the complexity of the algorithm. The recurrence is the same as the standard recurrence for MERGE-SORT , and the overall time is $\Theta(n \cdot \lg n)$.
