#### A\* Search

- Computes optimal g-values for relevant states
- at any point of time:

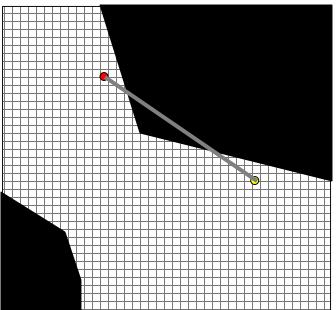

one popular heuristic function – Euclidean distance

minimal cost from s to  $s_{goal}$ 

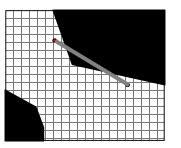

- Heuristic function must be:
  - admissible: for every state s,  $h(s) \le c^*(s, s_{goal})$
  - consistent (satisfy triangle inequality):

 $h(s_{goal}, s_{goal}) = 0$  and for every  $s \neq s_{goal}$ ,  $h(s) \leq c(s, succ(s)) + h(succ(s))$ 

admissibility provably follows from consistency and often (not always) consistency follows from admissibility

- For X-connected grids:
  - Euclidean distance

- Manhattan distance:  $h(x,y) = abs(x-x_{goal}) + abs(y-y_{goal})$
- Diagonal distance:  $h(x,y) = max(abs(x-x_{goal}), abs(y-y_{goal}))$
- More informed distances???

Which heuristics are admissible for 4-connected grid? 8-connected grid?

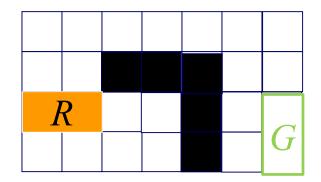

• For planning problems higher than 2D

Example:

consider planning for a non-circular robot that can move in any direction (omnidirectional)

Non-circular robot

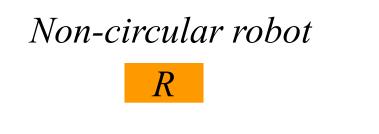

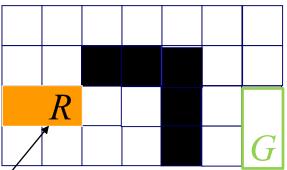

• For planning problems higher than 2D

Example:

consider planning for a non-circular robot that can move in any direction (omnidirectional)

Grid-based representation for planning: x,y, $\Theta$  for some reference point on the robot x,y are on 8-connected grid  $\Theta$  – discretized into 8 angles

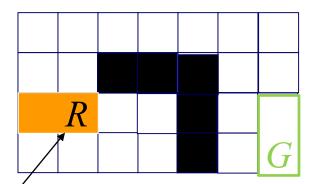

• For planning problems higher than 2D

Example:

consider planning for a non-circular robot that can move in any direction (omnidirectional)

R

Grid-based representation for planning: x,y, $\Theta$  for some reference point on the robot x,y are on 8-connected grid  $\Theta$  – discretized into 8 angles

Carnegie Mellon University

How many states?

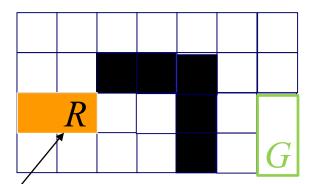

What heuristic we can use?

• For planning problems higher than 2D

Example:

consider planning for a non-circular robot that can move in any direction (omnidirectional)

Grid-based representation for planning: x,y, $\Theta$  for some reference point on the robot x,y are on 8-connected grid  $\Theta$  – discretized into 8 angles

Any ideas for heuristics

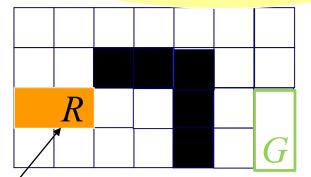

• For planning problems higher?

Example: consider planning for a non-c direction (omnidirectional)

*How about cost-to-goal* distances for the reference point in 2D (accounting for obstacles)?

Non-circular robot

R

Grid-based representation for planning:  $x,y,\Theta$  for some reference point on the robot x, y are on 8-connected grid  $\Theta$  – discretized into 8 angles

*How can we compute them?* 

• For planning problems his

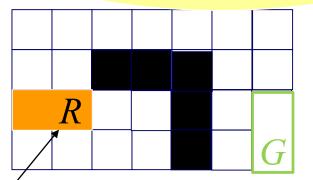

Example: consider planning for a non-c direction (omnidirectional)

Non-circular robot

R

How about cost-to-goal distances for the reference point in 2D (accounting for obstacles)?

Are these admissible?

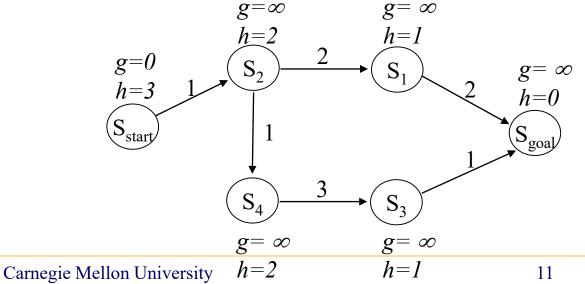

Grid-based representation for planning: x,y, $\Theta$  for some reference point on the robot x,y are on 8-connected grid  $\Theta$  – discretized into 8 angles

- Searching from the goal towards the start state

#### Examples: Heuristics via Low-D Search

• Planning in  $(x, y, z, \Theta, v)$  with heuristics = 3D (x, y, z) distances accounting for obstacles

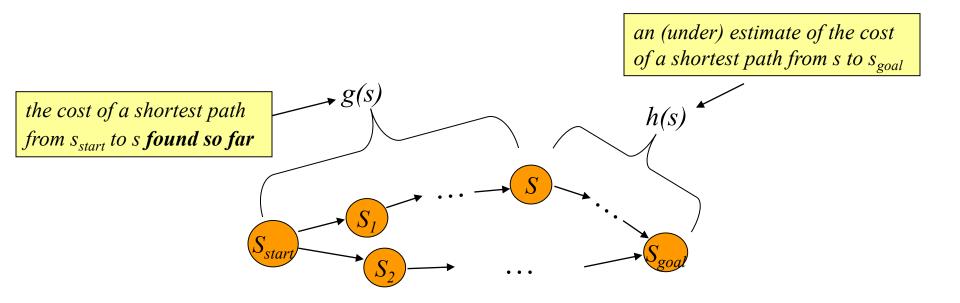

[MacAllisteret et al., ICRA'13]

• Planning for 7DOF arm with heuristics = 3D(x,y,z) distances for end-effector

[Cohen et al., IROS'13]

- Uninformed A\*: expands states in the order of *g* values
- A\*: expands states in the order of f = g + h values
- Weighted A\*: expands states in the order of  $f = g + \varepsilon h$ values,  $\varepsilon > l =$  bias towards states that are closer to goal

• Uninformed A\*: expands states in the order of g values

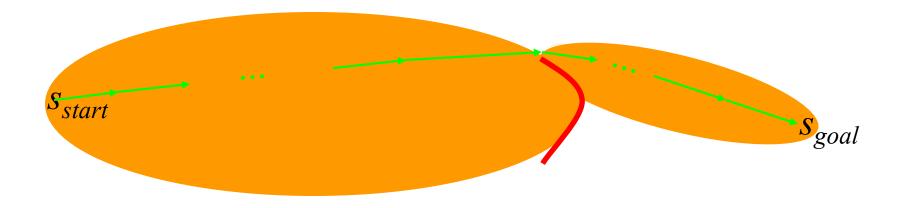

What are the states expanded?

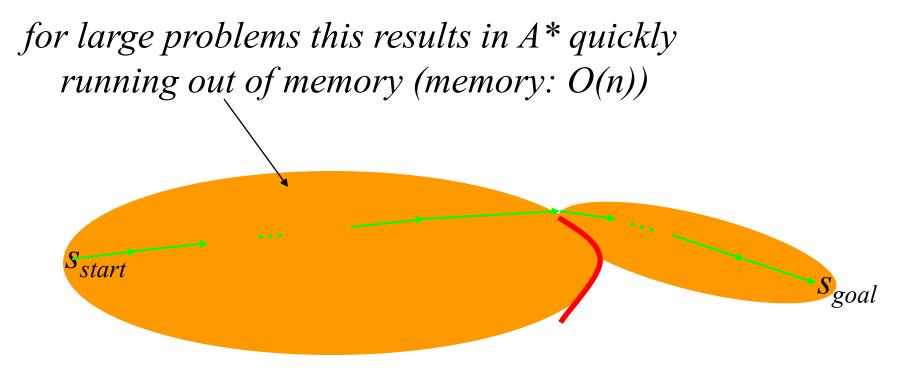

Sgoal

• A\*: expands states in the order of f = g + h values

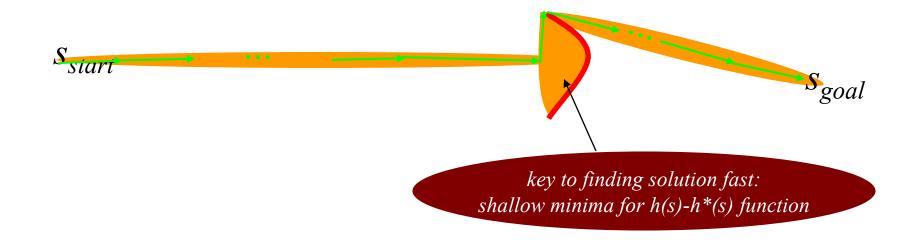

• A\*: expands states in the order of f = g + h values

• Weighted A\*: expands states in the order of  $f = g + \varepsilon h$ values,  $\varepsilon > 1$  = bias towards states that are closer to goal

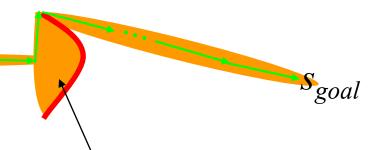

what states are expanded?

• Weighted A\*: expands states in the order of  $f = g + \varepsilon h$ values,  $\varepsilon > 1$  = bias towards states that are closer to goal

No one knows. Topic for research.

key to finding solution fast: \_shallow minima for h(s)-h\*(s) function

S<sub>siart</sub>

- Weighted A\* Search:
  - trades off optimality for speed
  - ε-suboptimal:

 $cost(solution) \leq \varepsilon cost(optimal solution)$ 

- in many domains, it has been shown to be orders of magnitude faster than A\*
- research becomes to develop a heuristic function that has shallow local minima

#### Few Properties of Heuristic Functions

• Useful properties to know:

- 
$$h_1(s)$$
,  $h_2(s)$  – consistent, then:  
 $h(s) = max(h_1(s), h_2(s))$  – consistent

- if A\* uses  $\varepsilon$ -consistent heuristics:

 $h(s_{goal}) = 0$  and  $h(s) \le \varepsilon c(s, succ(s)) + h(succ(s) \text{ for all } s \neq s_{goal},$ then A\* is  $\varepsilon$ -suboptimal:

 $cost(solution) \leq \varepsilon \ cost(optimal \ solution)$ 

- weighted  $A^*$  is  $A^*$  with  $\varepsilon$ -consistent heuristics

What is  $\varepsilon$ ? Proof?

-  $h_1(s)$ ,  $h_2(s)$  - consistent, then:  $h(s) = h_1(s) + h_2(s) - \varepsilon$ -consistent

# What You Should Know...

- Common heuristic functions for X-connected grids
   Euclidean distance, Manhattan distance, Diagonal distance, etc.
- Be able to design and implement heuristics for high-D planning (e.g., heuristics computed by low-d search)
- Weighted A\* and its properties
- Backward A\*
- How to combine heuristics, properties, *E*-consistent heuristics
