

# Lecture 15: Implementing a Symbolic Model Checker

---

- Representing Transition Relations
- Implementing Basic CTL Operators
- Fairness Constraints
- Buchi Automata
- Omega Regular Languages
- Checking Language Containment

# How To Build a CTL Model Checker

---

The following papers describe how to build a Symbolic Model Checker including fairness constraints:

- J. R. Burch, E. M. Clarke, K. L. McMillan, D. L. Dill, and J. Hwang. Symbolic model checking:  $10^{20}$  states and beyond. *Information and Computation*, 98(2):pages 142–170, 1992.
- J. R. Burch, E. M. Clarke, D. E. Long, K. L. McMillan, and D. L. Dill. Symbolic model checking for sequential circuit verification. *IEEE Transactions on Computer-Aided Design of Integrated Circuits*, 13(4):401–424, 1994.

# Representing Transition Relations

---

How to represent state-transition graphs with *Ordered Binary Decision Diagrams*:

Assume that system behavior is determined by  $n$  boolean state variables  $v_1, v_2, \dots, v_n$ .

The Transition relation  $N$  will be given as a boolean formula in terms of the state variables:

$$N(v_1, \dots, v_n, v'_1, \dots, v'_n)$$

where  $v_1, \dots, v_n$  represents the current state and  $v'_1, \dots, v'_n$  represents the next state.

Now convert  $N$  to a OBDD!!

# Symbolic Model Checking

---

*Check* takes a CTL formula as its argument and returns the OBDD for the set of states that satisfy the formula:

If  $f$  is an atomic proposition  $v_i$ , then  $Check(f)$  is simply the OBDD for  $v_i$ .

Formulas of the form  $f \vee g$  and  $\neg f$  are handled using the standard OBDD algorithms for these connectives.

**EX**  $f$ , **E**[ $f$  **U**  $g$ ], and **EG**  $f$  are handled by auxiliary procedures:

$$\begin{aligned} Check(\mathbf{EX} f) &= CheckEX(Check(f)) \\ Check(\mathbf{E}[f \mathbf{U} g]) &= CheckEU(Check(f), Check(g)) \\ Check(\mathbf{EG} f) &= CheckEG(Check(f)) \end{aligned}$$

**AX**  $f$ , **A**[ $f$  **U**  $g$ ] and **AG**  $f$  are rewritten in terms of above operators.

# Symbolic Model Checking (Cont.)

---

*CheckEX* is simple since **EX**  $f$  is true in a state if it has a successor in which  $f$  is true.

$$\text{CheckEX}(f(\bar{v})) = \exists \bar{v}' [f(\bar{v}') \wedge R(\bar{v}, \bar{v}')].$$

Given OBDDs for  $f$  and  $R$ , the OBDD for

$$\exists \bar{v}' [f(\bar{v}') \wedge R(\bar{v}, \bar{v}')].$$

is computed as described in the first lecture.

## Symbolic Model Checking (Cont.)

---

$CheckEU(f(\bar{v}), g(\bar{v}))$  is given by

$$\mathbf{lfp} Z(\bar{v}) [g(\bar{v}) \vee (f(\bar{v}) \wedge CheckEX(Z(\bar{v})))] .$$

The function  $Lfp$  is used to compute the sequence of approximations  $Z_0, Z_1, \dots$ .

This sequence converges to  $\mathbf{E}[f \mathbf{U} g]$  in a finite number of steps.

The OBDD for  $Z_{i+1}$  is computed from the OBDDs for  $f$ ,  $g$ , and  $Z_i$ .

Since OBDDs are a canonical form for boolean functions, convergence is easy to detect.

When  $Z_i = Z_{i+1}$ ,  $Lfp$  terminates. The state set for  $\mathbf{E}[f \mathbf{U} g]$  is given by the OBDD for  $Z_i$ .

## Symbolic Model Checking (Cont.)

---

*CheckEG* is similar. In this case, the procedure is based on the greatest fixpoint characterization for the CTL operator **EG**:

$$\text{CheckEG}(f(\bar{v})) = \mathbf{gfp} \ Z(\bar{v}) \ [f(\bar{v}) \wedge \text{CheckEX}(Z(\bar{v}))]$$

Given the OBDD for  $f$ , the function Gfp is used to compute the OBDD for **EG**  $f$ .

# CTL with Fairness Constraints

---

A *fairness constraint* can be an arbitrary formula of CTL.

Let  $H = \{h_1, \dots, h_n\}$  be a set of such fairness constraints.

A path  $p$  is *fair* with respect to  $H$  if each  $h_i \in H$  holds *infinitely often* on  $p$ .

The path quantifiers in CTL formulas are restricted to fair paths.

# EG with Fairness Constraints

---

Consider the formula  $\mathbf{EG} f$  with the set of fairness constraints  $H$ .

This formula will be true at a state  $s$  if there is a path  $p$  starting at  $s$  such that

- $f$  holds globally on  $p$ , and
- each formula in  $H$  holds infinitely often on  $p$ .

## The operator EG (Cont.)

---

Let  $S$  be the largest set of states with the following two properties:

1. all of the states in  $S$  satisfy  $f$ , and
2. for all fairness constraints  $h_k \in H$  and all states  $s \in S$ 
  - there is a non-empty sequence of states from  $s$  to a state in  $S$  satisfying  $h_k$ , and
  - all states in the sequence satisfy the formula  $f$ .

It can be shown that each state in  $S$  is the beginning of a path on which  $f$  is always true.

Furthermore, every formula in  $H$  holds infinitely often on this path.

## The operator EG (Cont.)

---

It follows that  $\mathbf{EG} f$  can be expressed as a greatest fixed point of a predicate transformer:

$$\mathbf{EG} f = \mathbf{gfp} S \left[ f \wedge \bigwedge_{k=1}^n \mathbf{EX}(\mathbf{E}[f \mathbf{U} S \wedge h_k]) \right]$$

This formula can be used to compute the set of states that satisfy  $\mathbf{EG} f$ .

# Other Operators

---

Checking the formulas  $\mathbf{EX} f$  and  $\mathbf{E}[f \mathbf{U} g]$  under fairness constraints is simpler.

The set of all states which are the start of some fair computation is

$$fair = \mathbf{EG} true.$$

Hence,

$$\begin{aligned}\mathbf{EX}(f) &= \mathbf{EX}(f \wedge fair), \\ \mathbf{E}[f \mathbf{U} g] &= \mathbf{E}[f \mathbf{U} g \wedge fair]\end{aligned}$$

Remaining CTL operators can be expressed in terms of  $\mathbf{EX}$ ,  $\mathbf{EG}$ , and  $\mathbf{EU}$ . For example,

$$\mathbf{A}[f \mathbf{U} g] \equiv \neg \mathbf{E}[\neg g \mathbf{U} \neg f \wedge \neg g] \wedge \neg \mathbf{EG} \neg g$$

# $\omega$ -automata

---

There are many types of  $\omega$ -automata. However, we will only consider deterministic Büchi automata.

A finite *Büchi automaton* is a 5-tuple

$$M = \langle K, p_0, \Sigma, \Delta, A \rangle,$$

where

- $K$  is a finite set of *states*
- $p_0 \in K$  is the *initial state*
- $\Sigma$  is a finite *alphabet*
- $\Delta \subseteq K \times \Sigma \times K$  is the *transition relation*
- $A \subseteq K$  is the *acceptance set*.

$M$  is *deterministic* if for all  $p, q_1, q_2 \in K$  and  $\sigma \in \Sigma$ , if  $\langle p, \sigma, q_1 \rangle, \langle p, \sigma, q_2 \rangle \in \Delta$  then  $q_1 = q_2$ .

# Language Acceptance

---

An infinite sequence of states  $p_0p_1p_2 \dots \in K^\omega$  is a *path* in  $M$  if there exists an infinite sequence  $a_0a_1a_2 \dots \in \Sigma^\omega$  such that  $\forall i \geq 0 : \langle s_i, a_i, s_{i+1} \rangle \in \Delta$ .

Let  $p = p_0p_1p_2 \dots \in K^\omega$  be a path in  $M$ . The *infinitary set* of  $p$  is the set of states that occur infinitely often on  $p$ .

A sequence  $a_0a_1a_2 \dots \in \Sigma^\omega$  is *accepted* by  $M$  if there is a corresponding path  $p = p_0p_1p_2 \dots \in K^\omega$  such that the infinitary set of  $p$  contains at least one element of  $A$ .

The set of sequences accepted by an automaton  $M$  is called the *language of  $M$*  and is denoted  $\mathcal{L}(M)$ .

# Büchi Automata Examples

---

The alphabet for these examples is the set  $\Sigma = \{p, q, r\}$ . States in the acceptance set are shaded.

- This automaton accepts infinite length strings with the property that every occurrence of  $p$  is eventually followed by an occurrence of  $q$ .

- This automaton accepts infinite length strings with the property that  $p$  occurs almost always in the string.

# Product Construction

---

Let  $M$  and  $M'$  be two Büchi automata over the same alphabet  $\Sigma$ .

Consider the Kripke structure

$$\mathcal{K}(M, M') = (AP, K \times K', \langle p_0, p'_0 \rangle, L, R),$$

where

- $AP = \{q, q'\}$  is the set of atomic propositions
- $\langle s, s' \rangle \models q$  iff  $s \in A$
- $\langle s, s' \rangle \models q'$  iff  $s' \in A'$
- $\langle s, s' \rangle R \langle r, r' \rangle$  iff  $\exists a \in \Sigma : \langle s, a, r \rangle \in \Delta$  and  $\langle s', a, r' \rangle \in \Delta'$ .

# Checking Containment

---

It is possible to show that, if  $M'$  is deterministic,

$$\mathcal{L}(M) \subseteq \mathcal{L}(M') \Leftrightarrow K(M, M') \models \mathbf{A}[\varphi q \Rightarrow \varphi q']$$

The above formula is in CTL\* but not in CTL. However, it belongs to a class of formulas which can be checked in polynomial time.

In fact,  $\mathbf{A}[\varphi q \Rightarrow \varphi q']$  is equivalent to  $\mathbf{AG} \mathbf{AF} q'$  under the fairness constraint “infinitely often  $q$ ”.

Checking this formula with the given fairness constraint can be handled by the technique described previously.
