Wireless Networks and Applications
Lecture 12: Ad Hoc Networks

Peter Steenkiste

Spring Semester 2020
<http://www.cs.cmu.edu/~prs/wirelessS20/>

Peter A. Steenkiste

1

Ad Hoc Routing

- Definition and challenges
- Routing:
 - » Classes: proactive versus reactive routing
 - » Proactive, table based routing: DSDV
 - » Reactive routing DSR
 - » Geographic routing: GPSR
- Discussion
- Structured as a survey
 - » But a bit longer since it covers more material

Peter A. Steenkiste

2

Ad Hoc Networking

- Goal: Communication between wireless nodes
 - » No infrastructure – network must be self-configuring
- It may require multiple hops to reach a destination
 - » Nodes are traffic sources, sinks and forwarders

Peter A. Steenkiste

3

Ad Hoc Networking Challenging

- All the challenges of wireless, and more:
 - » Decentralized: nobody is in charge – no planning!
 - » No fixed infrastructure, random network design
 - » Generic ad hoc can be arbitrarily bad: limited batteries, malicious nodes, high mobility, low density, ..
- Precise challenges depend on the application domain, e.g., vehicular networks versus first-responder networks versus sensor networks
 - » Domain focus typically simplifies the problem
 - » Most research papers address the complex general case
- The big challenge: Routing

Peter A. Steenkiste

4

Traditional Routing vs Ad Hoc

- **Traditional wired network:**

- » Well-structured
- » $\sim O(N)$ nodes & links
- » All links work equally well
- » Sensible topology
- » Links are independent

- **Ad Hoc wireless network**

- » N^2 links - but many stink!
- » Topology may be really weird
- » Links interfere with each other
- » Dynamic link conditions affect link quality unpredictably
 - So the topology also changes constantly!

Peter A. Steenkiste

5

Forwarding Packets is expensive

- **Assume link throughput is X**

- » X depends on the WiFi version, distance, fading, ...

- **What is the throughput of a chain?**

- » Basic: $A \rightarrow B \rightarrow C$
- » Or: $A \rightarrow B \rightarrow C \rightarrow D$
- » Or: $A \rightarrow B \rightarrow C \rightarrow D \rightarrow E \dots$

- **Considering:**

- » Wired versus wireless
- » Assume minimum power for radios.
- » Now assume a dense network, i.e., all radios can hear each other
- » Now assume dynamic link conditions, mobility, ..

Peter A. Steenkiste

6

2 Simple Examples

$A \rightarrow B \rightarrow C \rightarrow D \rightarrow E \rightarrow F \rightarrow G \rightarrow D$

Peter A. Steenkiste

7

Ad Hoc Routing

- **Classes: proactive versus reactive routing**
- **Proactive, table based routing: DSDV**
- **Reactive routing DSR**
- **Geographic routing: GPSR**

Peter A. Steenkiste

8

Proactive or Table-based Protocols

- **Proactive: routers maintain routes independently of the need for communication**
 - » Similar to wired networking – uses forwarding table
- **Route update messages are sent periodically or when network topology changes**
- **Low latency – forwarding information is always readily available**
- **Bandwidth might get wasted due to periodic updates**

Peter A. Steenkiste

9

Reactive or On-Demand Routing

- **Routers discover a route only when there is data to be sent**
- **Saves energy and bandwidth during periods of inactivity or low activity**
- **Route discovery introduces significant delay for the first packet of a new transfer**
- **Bad if many nodes send packets to many destinations at random times or in unstable networks**

Peter A. Steenkiste

10

Ad Hoc Routing

- **Classes: proactive versus reactive routing**
- **Proactive, table based routing: DSDV**
- **Reactive routing DSR**
- **Geographic routing: GPSR**

Peter A. Steenkiste

11

Packet Forwarding versus Routing

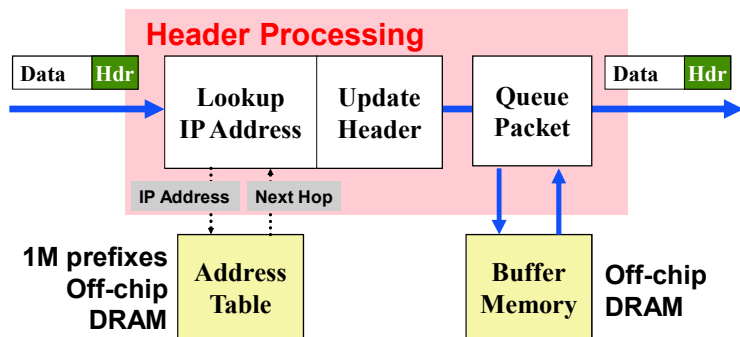

Destination Address	Port
IP1	1
IP2	2
IP3	2
IP4	2
IP5	3

Peter A. Steenkiste

- **Routing finds a path between two end-points**
- **Forwarding receives a packet and decides which egress port to send it out on**
- **Most networks use a routing protocol to pre-calculate paths between every pair of nodes**
 - » Routers put the result in a forwarding table
- **Forwarding only requires a lookup in the forwarding table – fast!**

12

Generic Router Architecture

Peter A. Steenkiste

13

13

Traditional Routing Solutions

- **Link state routing**
 - » Each router obtains a full topology of the network by having nodes periodically flood connectivity information
 - » Each router then uses Dijkstra's algorithm to locally calculate its forwarding table
 - » Bad fit for ad hoc: LS flooding creates a lot of traffic and relies on all routers having a consistent view of network
- **Distance vector**
 - » Each router tells its neighbors its shortest path to each destination
 - » Routers then use the "best" option provided to them
 - » Based on the Bellman-Ford algorithm
 - » More promising for ad hoc: has lower routing overhead
 - » Challenge is how to avoid routing loops (details omitted)

Peter A. Steenkiste

Background

14

Routes from Node A

Forwarding Table for A		
Dest	Cost	Next Hop
A	0	A
B	4	B
C	6	E
D	7	B
E	2	E
F	5	E

- **Set of shortest paths forms tree**
 - » Shortest path spanning tree
- **Solution is not unique**
 - » E.g., A-E-F-C-D also has cost 7

Peter A. Steenkiste

Background

15

Different View: How to Get to Node C

Forwarding Table for E		
Dest	Cost	Next Hop
C	4	F

Forwarding Table for F		
Dest	Cost	Next Hop
C	1	C

Forwarding Table for C		
Dest	Cost	Next Hop
C	-	-

Forwarding Table for A		
Dest	Cost	Next Hop
C	6	E

Forwarding Table for B		
Dest	Cost	Next Hop
C	2	F

Forwarding Table for D		
Dest	Cost	Next Hop
C	1	C

Peter A. Steenkiste

Background

16

Distance-Vector Method

Initial Table for A		
Dest	Cost	Next Hop
A	0	A
B	4	B
C	∞	-
D	∞	-
E	2	E
F	6	F

- Router periodically exchanges tables with neighbors
 - » Contains the cost and next hop of best known path to all destination
- Routers pick the best of the candidates paths
 - » May be the path it is currently using already

Peter A. Steenkiste

Background

17

Destination-Sequenced Distance Vector (DSDV)

- By Perkins and Bhagvat
- DV protocol specifically designed for wireless
 - » Exchange of routing tables
 - » Routing table: the way to the destination, plus the cost
- Each node advertises its presence and tables
 - » Maintains fresh routes by periodically sending updates to neighbors
 - » Update for each destination: hop count, sequence number
- Uses sequence number to avoid loops
 - » Advertisements for each destination include sequence number that is incremented for each update
 - » Since loops are created by advertisements based on old routing information, they can be detected

Peter A. Steenkiste

18

DSDV Properties

- Keep the simplicity of Distance Vector
- Guarantees Loop Freeness
 - » While adding minimal overhead
- Allow fast reaction to topology changes
 - » Make immediate route advertisement on significant changes in routing table
- Drawbacks:
 - » Overhead can be significant under dynamic conditions and mobility
 - » Many ad hoc networking scenarios do not require all-all connectivity, so some effort is wasted

Based on: cone.informatik.uni-freiburg.de/teaching/vorlesung/manet-s07/exercises/DSDV.ppt

Peter A. Steenkiste

19

Overview

- Ad hoc networking concept
- Proactive versus reactive routing
- Proactive, table based routing: DSDV
- Reactive routing DSR
- Geographic routing: GPSR
- Wireless link metrics
- Ad hoc networking examples

Peter A. Steenkiste

20

Dynamic Source Routing (DSR) Key Features

- **On-demand route discovery finds route only when it is needed**
 - » Avoid overhead of periodic route advertisements
- **Uses source routing: path information is stored in the packet header**
- **DSR control functions:**
 - » Route discovery: senders obtain route to destination
 - » Route maintenance: detect changes in topology and update routes that are affected
 - » Route caching: nodes cache route information to avoid route discovery for every packet
 - Caching can be done on sender and intermediate routers
 - Flush broken routes from cache

Peter A. Steenkiste

21

DSR Route Discovery

- **Source broadcasts a route-request towards the destination**
 - » The request includes a (partial) path from source to destination
- **Each node forwards the request by adding own address to the path and re-broadcasting**
- **Requests propagate outward until:**
 - » The destination is found, or
 - » A node that has a route to the destination is found

Peter A. Steenkiste

22

Route Request is Re-Broadcasted until Destination is Reached

Peter A. Steenkiste

23

C Transmits a Packet to F

Peter A. Steenkiste

24

Forwarding Route Requests

- **A request is forwarded by a node if:**
 - » Node is not the destination
 - » Node not already listed in recorded source route
 - » Node has not seen request with same sequence number
 - » IP TTL field may be used to limit scope
- **Destination copies selected route into a Route-reply packet and sends it back to Source**
 - » I.e., route reply uses reverse path of the route selected by the destination
 - » Destination can choose one of the paths, e.g., first path (with shortest delay)

Peter A. Steenkiste

25

Route Cache

- **All source routes learned by a node are kept in a Route Cache**
 - » Routes are learned by overhearing route requests/responses
 - » Reduces cost of route discovery
- **If an intermediate node receives a route request for a destination and has an entry for the destination in its route cache, it**
 - » Responds to the request using the cached information
 - » Does not propagate the request any further
- **Nodes use their local route cache when asked to send a data packet**
 - » If route is missing, they initiate a route request

Peter A. Steenkiste

26

Basic Route Maintenance

- **When forwarding a packet, each sender must get an acknowledgement from the next hop**
 - » Will retransmit the packet up to a limit if needed
- **If no ACK is received it drops the packet and notifies the sender A of the broken link**
- **A removes the route from its route cache and ..**
 - » Intermediate nodes also remove any cached entries to E
- **Will do a new route discovery when it sends another packet to E**
 - » It is left up to TCP to recover from the packet loss

Peter A. Steenkiste

27

Discussion

- **Source routing is good for certain types of networks and traffic loads**
 - » For example, stable traffic flows and/or a small number of sender-receiver pairs
 - » Stable network topologies, e.g., with limited mobility
- **Periodic messages are avoided**
- **Significant delay for the first packet to a destination**
 - » Also, need to buffer packets

Peter A. Steenkiste

28

Overview

- Ad hoc networking concept
- Proactive versus reactive routing
- Proactive, table based routing: DSDV
- Reactive routing DSR
- Geographic routing: GPSR
- Wireless link metrics
- Ad hoc networking examples

Peter A. Steenkiste

29

Greedy Perimeter Stateless Routing (GPSR)

- Use *positions* of neighboring nodes and packet destination to forward packets
 - No connectivity or global topology is assumed – no forwarding or path information anywhere!
 - Nodes are assumed to know their location
 - Need a mechanism for address-to-location look up
- Two forwarding techniques is used
 - *Greedy forwarding*, if possible
 - *Perimeter forwarding*, otherwise

Peter A. Steenkiste

30

GPSR - Greedy forwarding

- A sender/forwarder x chooses to forward to a neighbor y such that $\{d_{xy} + d_{yD}\}$ is minimum

Peter A. Steenkiste

31

GPSR - Perimeter forwarding

- What happens if a node does not have a neighbor that is closer to the destination?
- Right Hand Rule: you forward the packet to your first neighbor clockwise around yourself
 - Traverse an interior region in *clockwise* edge order
 - Guaranteed to reach a (reachable) destination for planar graph

This sequence of edges traversed is called a *PERIMETER*

Peter A. Steenkiste

32

Discussion

- **Many variants:**
 - » Hybrid approaches mix different solutions
 - » Hierarchical: create a hierarchy of clusters
- **Many proposals for optimizations**
 - » Links use different frequencies, multiple radios, etc.
 - » Link metrics that consider interference level, ...
- **Best solutions is highly context dependent: density, traffic load, degree of mobility, ...**
- **Practical applications are rare by exist:**
 - » Mesh networking: wireless, last mile Internet access
 - » Challenging conditions: first responders, military, ..
 - » In the future maybe vehicular, drones, ...

Peter A. Steenkiste

33

Summary

- **Ad hoc networks face many challenges**
 - » Bad links, interference, mobility, ...
 - » Makes routing very challenging
 - » Limited support: hardware and driver limitations
- **Many proposals!**
 - » Proactive routing: variants of “wired” routing protocols
 - » Reactive routing: only establish a path when it is needed
 - » Geographic routing: use destination location info only
 - » Many variants and extensions
- **Specific challenges depend on the application domains**
 - » Mesh versus vehicular
 - » Active area of research
