

15-744: Computer Networking

L-12 Wireless Broadcast

Taking Advantage of Broadcast

- Opportunistic forwarding
- Network coding
- Assigned reading
 - XORs In The Air: Practical Wireless Network Coding
 - ExOR: Opportunistic Multi-Hop Routing for Wireless Networks

2

Outline

- Opportunistic forwarding (ExOR)
- Network coding (COPE)
- Combining the two (MORE)

3

Initial Approach: Traditional Routing

- Identify a route, forward over links
- Abstract radio to look like a wired link

4

Radios Aren't Wires

- Every packet is broadcast
- Reception is probabilistic

5

Exploiting Probabilistic Broadcast

- Decide who forwards after reception
- Goal: only closest receiver should forward
- Challenge: agree efficiently and avoid duplicate transmissions

6

Why ExOR Might Increase Throughput

- Best traditional route over 50% hops: $3(1/0.5) = 6$ tx
- Throughput $\cong 1/\#$ transmissions
- ExOR exploits lucky long receptions: 4 transmissions
- Assumes probability falls off gradually with distance

7

Why ExOR Might Increase Throughput

- Traditional routing: $1/0.25 + 1 = 5$ tx
- ExOR: $1/(1 - (1 - 0.25)^3) + 1 = 2.5$ transmissions
- Assumes independent losses

8

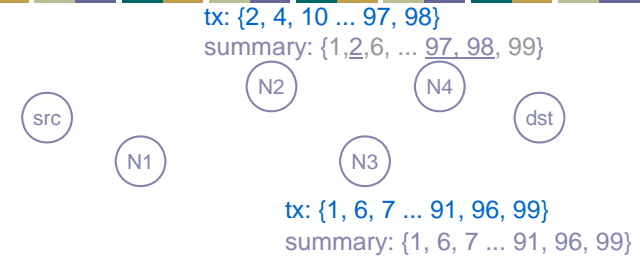

ExOR Batching

- Challenge: finding the closest node to have rx'd
- Send batches of packets for efficiency
- Node closest to the dst sends first
 - Other nodes listen, send remaining packets in turn
- Repeat schedule until dst has whole batch

9

Reliable Summaries

- Repeat summaries in every data packet
- Cumulative: what all previous nodes rx'd
- This is a gossip mechanism for summaries

10

Priority Ordering

- Goal: nodes "closest" to the destination send first
- Sort by ETX metric to dst
 - Nodes periodically flood ETX "link state" measurements
 - Path ETX is weighted shortest path (Dijkstra's algorithm)
- Source sorts, includes list in ExOR header

11

Using ExOR with TCP

- Batching requires more packets than typical TCP window

12

Summary

- ExOR achieves 2x throughput improvement
- ExOR implemented on Roofnet
- Exploits radio properties, instead of hiding them

13

Outline

- Opportunistic forwarding (ExOR)
- Network coding (COPE)
- Combining the two (MORE)

14

Background

- Famous butterfly example:

- All links can send one message per unit of time
 - Coding increases overall throughput

15

Background

- Bob and Alice

Require 4 transmissions

16

Background

- Bob and Alice

17

Coding Gain

- Coding gain = $4/3$

18

Throughput Improvement

- UDP throughput improvement \sim a factor $2 > 4/3$ coding gain

19

Coding Gain: more examples

With opportunistic listening, coding gain = $2N/(1+N) \rightarrow 2$.
 With opportunistic listening, coding gain + MAC gain $\rightarrow \infty$

20

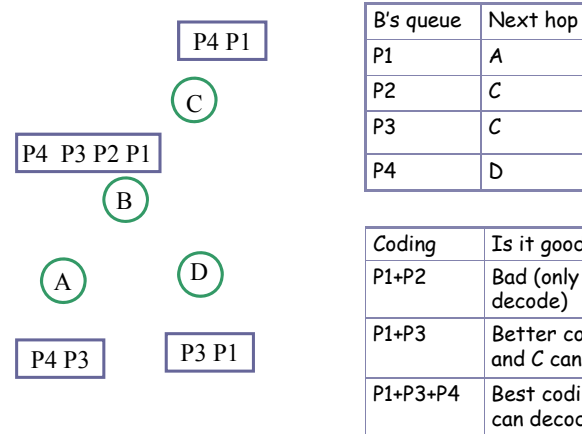

COPE (Coding Opportunistically)

- Overhear neighbors' transmissions
- Store these packets in a **Packet Pool** for a short time
- Report the packet pool info. to neighbors
- Determine what packets to code based on the info.
- Send encoded packets

21

Opportunistic Coding

Packet Coding Algorithm

- When to send?
 - Option 1: delay packets till enough packets to code with
 - Option 2: never delaying packets -- when there's a transmission opportunity, send packet right away
- Which packets to use for XOR?
 - Prefer XOR-ing packets of similar lengths
 - Never code together packets headed to the same next hop
 - Limit packet re-ordering
 - XORing a packet as long as all its nexthops can decode it with a high enough probability

23

Packet Decoding

- Where to decode?
 - Decode at each intermediate hop
- How to decode?
 - Upon receiving a packet encoded with n native packets
 - find n-1 native packets from its queue
 - XOR these n-1 native packets with the received packet to extract the new packet

24

Prevent Packet Reordering

- Packet reordering due to async acks degrade TCP performance
- Ordering agent
 - Deliver in-sequence packets immediately
 - Order the packets until the gap in seq. no is filled or timer expires

25

Summary of Results

- Improve UDP throughput by a factor of 3-4
- Improve TCP by
 - wo/ hidden terminal: up to 38% improvement
 - w/ hidden terminal and high loss: little improvement
- Improvement is largest when uplink to downlink has similar traffic
- Interesting follow-on work using analog coding

26

Reasons for Lower Improvement in TCP

- COPE introduces packet re-ordering
- Router queue is small → smaller coding opportunity
 - TCP congestion window does not sufficiently open up due to wireless losses
- TCP doesn't provide fair allocation across different flows

27

Outline

- Opportunistic forwarding (ExOR)
- Network coding (COPE)
- **Combining the two (MORE)**

28

Use Opportunistic Routing

Opportunistic routing promises large increase in throughput

29

But

- Overlap in received packets → Routers forward duplicates

30

ExOR

- State-of-the-art opp. routing, ExOR imposes a global scheduler:
- Requires full coordination; every node must know who received what
- Only one node transmits at a time, others listen

31

Global Scheduling?

- Global coordination is too hard
- One transmitter

32

Global Scheduling?

Does opportunistic routing have to be so complicated?

33

MORE (Sigcomm07)

- Opportunistic routing with no global scheduler and no coordination
- We use random network coding
- Experiments show that randomness outperforms both current routing and ExOR

34

Go Random

Each router forwards random combinations of packets

Randomness prevents duplicates

No scheduler; No coordination

Simple and exploits spatial reuse

35

Random Coding Benefits Multicast

Without coding → source retransmits all 4 packets

36

Random Coding Benefits Multicast

Random coding is more efficient than global coordination

MORE

- Source sends packets in batches
- Forwarders keep all heard packets in a buffer
- Nodes transmit linear combinations of buffered packets

$$a \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} + b \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} + c \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} = \begin{bmatrix} a,b,c \end{bmatrix}$$

Can compute linear combinations and sustain high throughput!

$$1 \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} + 2 \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} + 3 \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} = \begin{bmatrix} 0,2,1 \end{bmatrix}$$

MORE

- Source sends packets in batches
- Forwarders keep all heard packets in a buffer
- Nodes transmit linear combinations of buffered packets

$$a \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} + b \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} + c \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} = \begin{bmatrix} a,b,c \end{bmatrix}$$

$$2 \begin{bmatrix} 4,1,3 \end{bmatrix} + 1 \begin{bmatrix} 0,2,1 \end{bmatrix} = \begin{bmatrix} 8,4,7 \end{bmatrix}$$

MORE

- Source sends packets in batches
- Forwarders keep all heard packets in a buffer
- Nodes transmit linear combinations of buffered packets

- Destination decodes once it receives enough combinations
 - Say batch is 3 packets

$$1 \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} + 3 \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} + 2 \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} = \begin{bmatrix} 1,3,2 \end{bmatrix}$$

$$5 \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} + 4 \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} + 5 \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} = \begin{bmatrix} 5,4,3 \end{bmatrix}$$

$$4 \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} + 5 \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} + 5 \begin{bmatrix} P_1 \\ P_2 \\ P_3 \end{bmatrix} = \begin{bmatrix} 4,5,5 \end{bmatrix}$$

- Destination acks batch, and source moves to next batch
