Intel x86 Processors

- **Dominate laptop/desktop/server market**
- **Evolutionary design**
  - Backwards compatible up until 8086, introduced in 1978
  - Added more features as time goes on

- **x86 is a Complex Instruction Set Computer (CISC)**
  - Many different instructions with many different formats
    - But, only small subset encountered with Linux programs
- **Compare: Reduced Instruction Set Computer (RISC)**
  - RISC: *very few* instructions, with *very few* modes for each
  - RISC can be quite fast (but Intel still wins on speed!)
  - Current RISC renaissance (e.g., ARM, RISCV), especially for low-power

x86 Clones: Advanced Micro Devices (AMD)

- **Historically**
  - AMD had followed just behind Intel
  - A little bit slower, a lot cheaper
- **Then**
  - Recruited top circuit designers from Digital Equipment Corp. and other downward trending companies
  - Built Opteron: tough competitor to Pentium 4
  - Developed x86-64, their own extension to 64 bits
- **Recent Years**
  - Intel got its act together
    - 1995-2011: Lead semiconductor “fab” in world
  - 2018-2024: back-and-forth with Samsung for #1 by $$
    - Back-and-forth with AMD on performance
  - Non-86 GPUs from Nvidia now dominate compute market

Levels of Abstraction

C programmer

```
#include <stdio.h>
int main(){
  int i, n = 10, t1 = 0, t2 = 1, nxt;
  for (i = 1; i <= n; ++i){
    printf("%d, ", t1);
    nxt = t1 + t2;
    t1 = t2;
    t2 = nxt; }
  return 0; }
```

Definitions

- **Architecture: (also ISA: instruction set architecture) The parts of a processor design that one needs to understand for writing assembly/machine code.**
  - Examples: instruction set specification, registers
- **Microarchitecture: Implementation of the architecture**
  - Examples: cache sizes and core frequency
- **Code Forms:**
  - Machine Code: The byte-level programs that a processor executes

  - Addresses (untyped pointers)

Register names

```
addq    %rbx,  %rax
```

is

```
rax += rbx
```

These are 64-bit registers, so we know this is a 64-bit add

x86-64 Integer Registers

%rax	%eax	%r8	%r8d
%rbx	%ebx	%r9	%r9d
%rcx	%ecx	%r10	%r10d

    - Encoded with 1, 2, or 4 bytes
  - ***Register:*** One of 16 integer registers
    - Example: **`%rax`**, **`%r13`**
    - But **`%rsp`** reserved for special use
    - Others have special uses for particular instructions

`%rax`

`%rcx`

`%rdx`

`%rbx`

`%rsi`

`%rdi`

`%rsp`

`%rbp`

`movq` Operand Combinations

	Source	Dest	Src,Dest	C Analog
`movq`	*Imm*	*Reg*	`movq $0x4,%rax`	`temp = 0x4;`
		Mem	`movq $-147,(%rax)`	`*p = -147;`

Today: Machine Programming I: Basics

- History of Intel processors and architectures
- Assembly Basics: Registers, operands, move
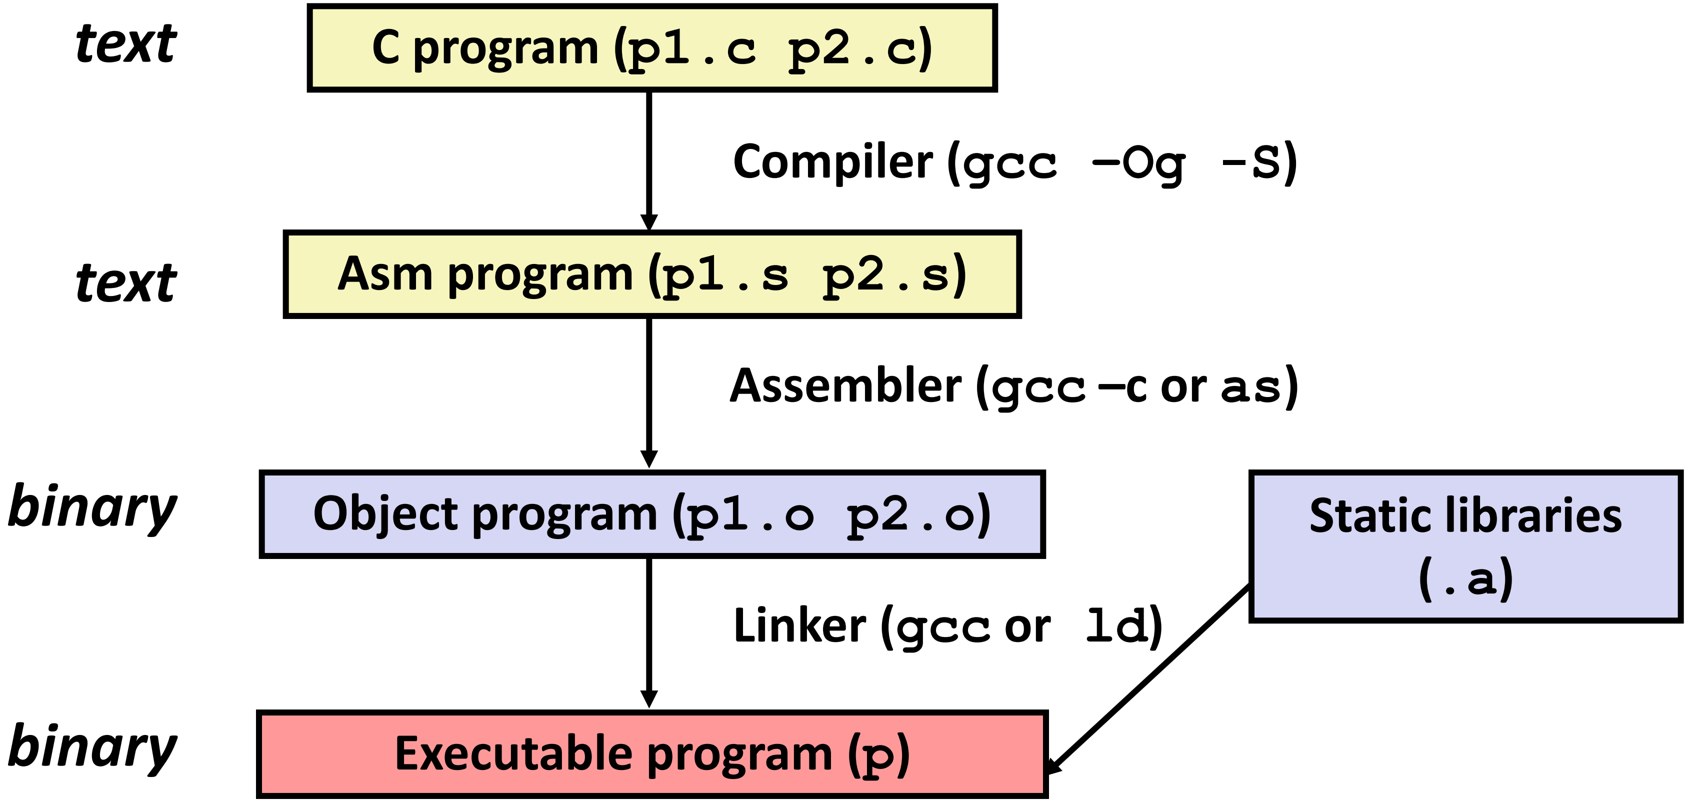
- Arithmetic & logical operations
- C, assembly, machine code

Turning C into Object Code

- Code in files `p1.c p2.c`
- Compile with command: `gcc –Og p1.c p2.c -o p`
  - Use debugging-friendly optimizations (`–Og`)
  - Put resulting binary in file `p`



Compiling Into Assembly

C Code (sum.c)

```
long plus(long x, long y);

void sumstore(long x, long y,
              long *dest)
{
    long t = plus(x, y);
    *dest = t;
}
```

Generated x86-64 Assembly

```
sumstore:
   pushq   %rbx
   movq    %rdx, %rbx
   call    plus
   movq    %rax, (%rbx)
   popq    %rbx
   ret
```

Obtain (on shark machine) with command

```
gcc -Og -S sum.c
```

Produces file `sum.s`

***Warning*: Will get very different results on non-Shark machines (Andrew Linux, Mac OS-X, …) due to different versions of gcc and different compiler settings.**

What it really looks like

```
        .globl  sumstore
        .type   sumstore, @function
sumstore:
.LFB35:
        .cfi_startproc
        pushq   %rbx
        .cfi_def_cfa_offset 16
        .cfi_offset 3, -16
        movq    %rdx, %rbx
        call    plus
        movq    %rax, (%rbx)
        popq    %rbx
        .cfi_def_cfa_offset 8
        ret
        .cfi_endproc
.LFE35:
        .size   sumstore, .-sumstore

    0xc3
```

- **Total of 14 bytes**
- **Each instruction 1, 3, or 5 bytes**
- **Starts at address `0x0400595`**

- **Assembler**
  - Translates `.s` into `.o`
  - Binary encoding of each instruction
  - Nearly-complete image of executable code
  - Missing linkages between code in different files
- **Linker**
  - Resolves references between files
  - Combines with static run-time libraries
    - E.g., code for **`malloc`**, **`printf`**
  - Some libraries are *dynamically linked*
    - Linking occurs when program begins execution

Machine Instruction Example

```
*dest = t;
```

```
movq %rax, (%rbx)
```

```
0x40059e:   48 89 03
```

- **C Code**
  - Store value **`t`** where designated by **`dest`**
- **Assembly**
  - Move 8-byte value to memory
    - Quad words in x86-64 parlance
  - Operands:

`t:`	Register **`%rax`**
`dest:`	Register **`%rbx`**
`*dest:`	Memory **`M[%rbx]`**

- **Object Code**
  - 3-byte instruction
  - Stored at address **`0x40059e`**

Disassembling Object Code

Disassembled

```

- **Disassembler**

  `objdump -d sum`

  - Useful tool for examining object code
  - Analyzes bit pattern of series of instructions
  - Produces approximate rendition of assembly code
  - Can be run on either `a.out` (complete executable) or `.o` file

Alternate Disassembly
