

Machine-Level Programming IV: Data

15-213/14-513/15-513: Introduction to Computer Systems
7th Lecture, February 7, 2023

Announcements

- **GCC Bootcamp (compilers and makefiles)**
 - Sunday 2/12
 - Details to be updated on piazza
 - Zoom link will be posted on piazza
 - Recording and slides will be posted afterwards
- **Bomb lab due Thursday (hopefully today will help with phase 6)**

Today

■ Arrays

- One-dimensional
- Multi-dimensional (nested)
- Multi-level

■ Structures

- Allocation
- Access
- Alignment

Reminder: Memory Organization

■ Memory locations do not have data types

- Types are implicit in how machine instructions *use* memory

■ Addresses specify byte locations

- Address of a larger datum is the address of its first byte
- Addresses of successive items differ by the item's size

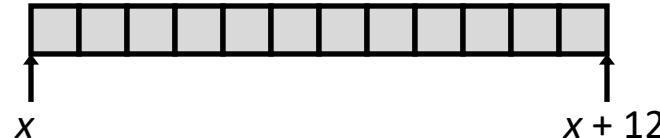

Address	chars	ints	longs
4000			
4001			
4002			
4003			
4004			
4005			
4006			
4007			
4008			
4009			
400A			
400B			
400C			
400D			
400E			
400F			

Array Allocation

■ C declaration *Type name[Length]* ;

- Array of data type *Type* and length *Length*
- Contiguously allocated region of $\text{Length} * \text{sizeof}(\text{Type})$ bytes in memory

```
char string[12];
```

```
int val[5];
```

```
double a[3];
```

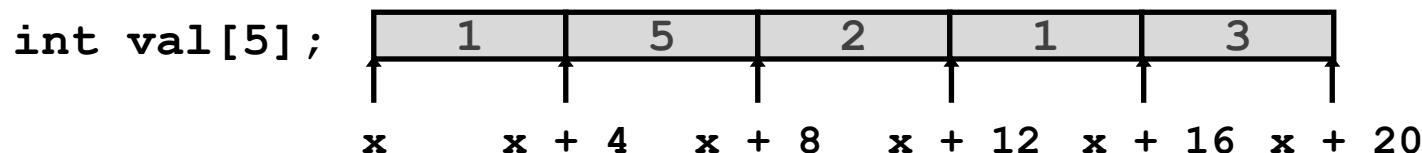

```
char *p[3];
```

Array Access

■ C declaration **Type name [Length];**

- Array of data type *Type* and length *Length*
- Identifier **name** acts like¹ a pointer to array element 0

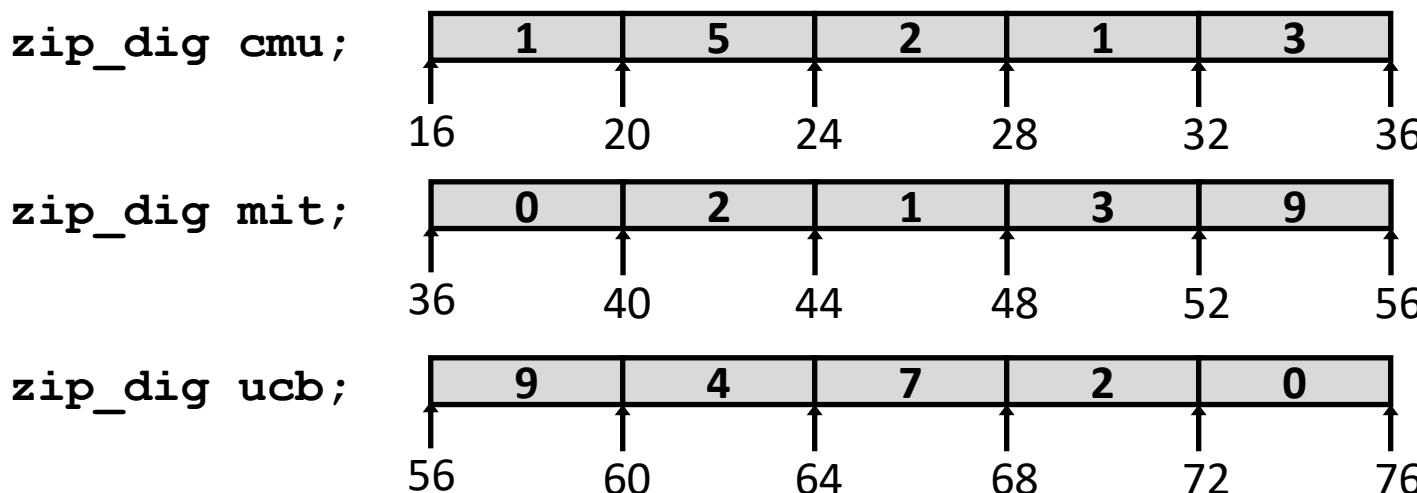

■ Expression	Type	Value	
<code>val[4]</code>	<code>int</code>	3	
<code>val[5]</code>	<code>int</code>	??	// access past end
<code>* (val+3)</code>	<code>int</code>	1	// same as <code>val[3]</code>
<code>val</code>	<code>int *</code>	<code>x</code>	
<code>val+1</code>	<code>int *</code>	<code>x + 4</code>	
<code>&val[2]</code>	<code>int *</code>	<code>x + 8</code>	// same as <code>val+2</code>
<code>val + i</code>	<code>int *</code>	<code>x + 4*i</code>	// same as <code>&val[i]</code>

¹ in most contexts (but not all)

Array Example

```
#define ZLEN 5
typedef int zip_dig[ZLEN];

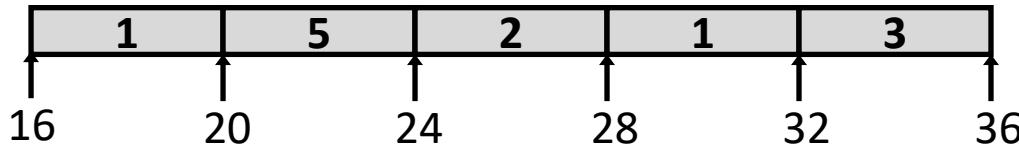

zip_dig cmu = { 1, 5, 2, 1, 3 };
zip_dig mit = { 0, 2, 1, 3, 9 };
zip_dig ucb = { 9, 4, 7, 2, 0 };
```

- Declaration “`zip_dig cmu`” equivalent to “`int cmu[5]`”
- Example arrays were allocated in successive 20 byte blocks
 - Not guaranteed to happen in general

Array Accessing Example

```
zip_dig cmu;
```

```
int get_digit
    (zip_dig z, int digit)
{
    return z[digit];
}
```

x86-64

```
# %rdi = z
# %rsi = digit
movl (%rdi,%rsi,4), %eax # z[digit]
```

- Register **%rdi** contains starting address of array
- Register **%rsi** contains array index
- Desired digit at **%rdi + 4*%rsi**
- Use memory reference (**%rdi, %rsi, 4**)

Array Loop Example

```
void zincr(zip_dig z) {
    size_t i;
    for (i = 0; i < ZLEN; i++)
        z[i]++;
}
```

```
# %rdi = z
movl    $0, %eax
jmp     .L3
.L4:
    addl    $1, (%rdi,%rax,4)
    addq    $1, %rax
.L3:
    cmpq    $4, %rax
    jbe     .L4
rep; ret
```

Array Loop Example

```
void zincr(zip_dig z) {
    size_t i;
    for (i = 0; i < ZLEN; i++)
        z[i]++;
}
```

```
# %rdi = z
movl    $0, %eax          # i = 0
jmp     .L3                # goto middle
.L4:                           # loop:
    addl    $1, (%rdi,%rax,4) # z[i]++
    addq    $1, %rax          # i++
.L3:                           # middle
    cmpq    $4, %rax          # i:4
    jbe     .L4                # if <=, goto loop
rep; ret
```

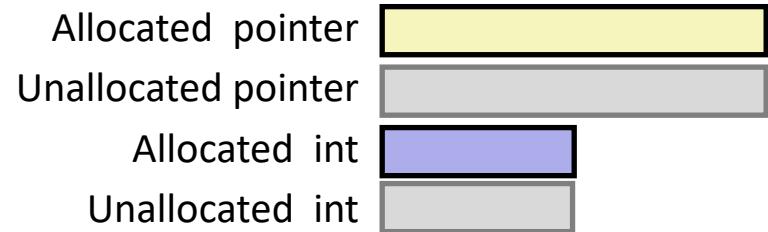

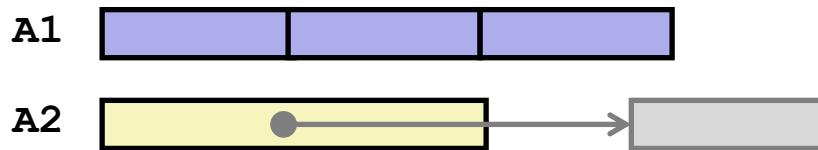

Understanding Pointers & Arrays #1

Decl	A1 , A2			*A1 , *A2

<code>int (*A3)[3]</code>	Y	N	8	Y	Y	12	Y	Y	4

Multidimensional (Nested) Arrays

■ Declaration

$T \ A[R][C];$

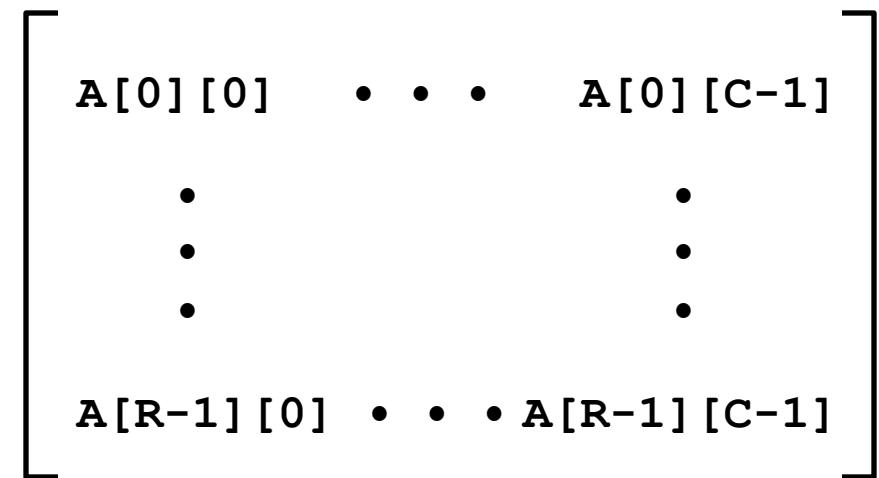

- 2D array of data type T
- R rows, C columns

■ Array Size

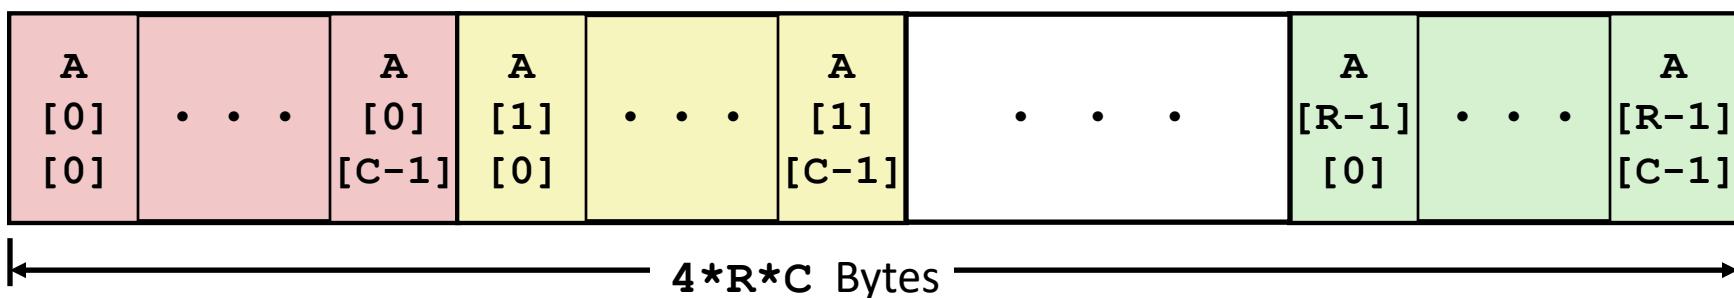

- $R * C * \text{sizeof}(T)$ bytes

■ Arrangement

- Row-Major Ordering

```
int A[R][C];
```

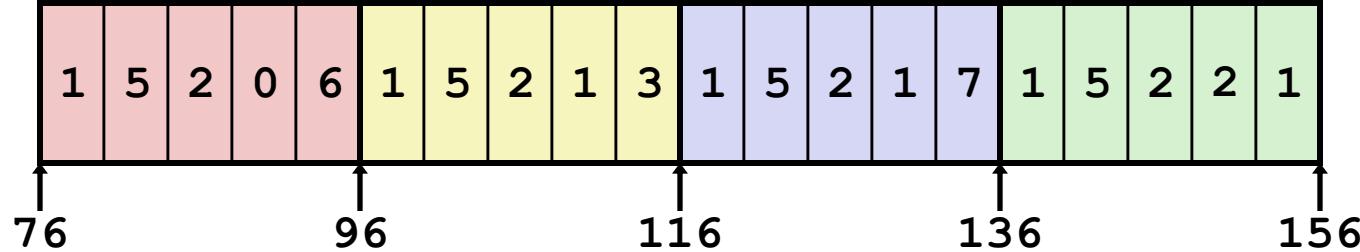

Nested Array Example

```
#define PCOUNT 4
typedef int zip_dig[5];

zip_dig pgh[PCOUNT] =
    {{1, 5, 2, 0, 6 },
     {1, 5, 2, 1, 3 },
     {1, 5, 2, 1, 7 },
     {1, 5, 2, 2, 1 }};
```

zip_dig
pgh[4];

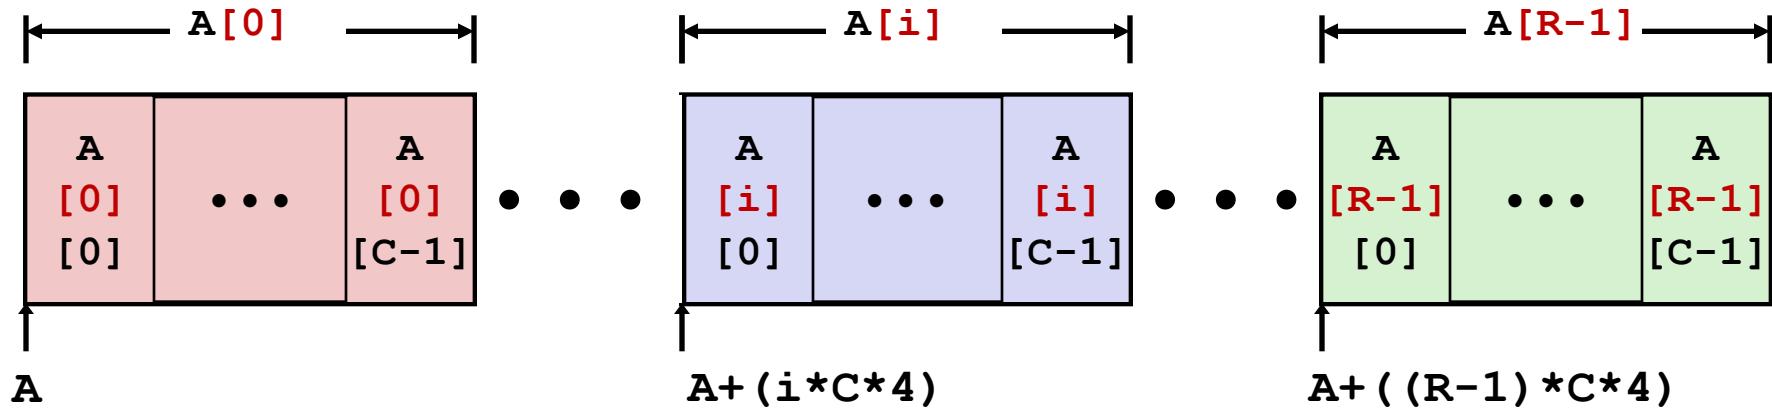

- “`zip_dig pgh[4]`” equivalent to “`int pgh[4][5]`”
 - Variable `pgh`: array of 4 elements, allocated contiguously
 - Each element is an array of 5 `int`’s, allocated contiguously
- “Row-Major” ordering of all elements in memory

Nested Array Row Access

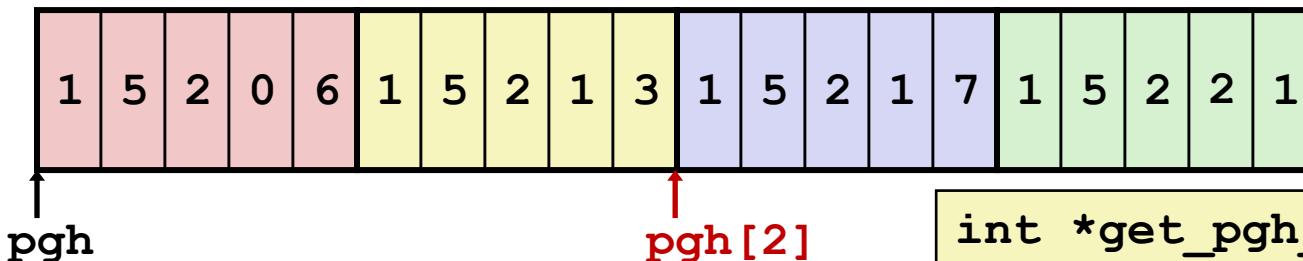

■ Row Vectors

- $\mathbf{A[i]}$ is array of C elements of type T
- Starting address $\mathbf{A} + \mathbf{i} * (\mathbf{C} * \mathbf{sizeof}(T))$

```
int A[R][C];
```

Nested Array Row Access Code

```
int *get_pgh_zip(int index)
{
    return pgh[index];
}
```

```
# %rdi = index
leaq (%rdi,%rdi,4),%rax # 5 * index
leaq pgh(%rax,4),%rax   # pgh + (20 * index)
```

■ Row Vector

- `pgh[index]` is array of 5 `int`'s
- Starting address `pgh+20*index`

■ Machine Code

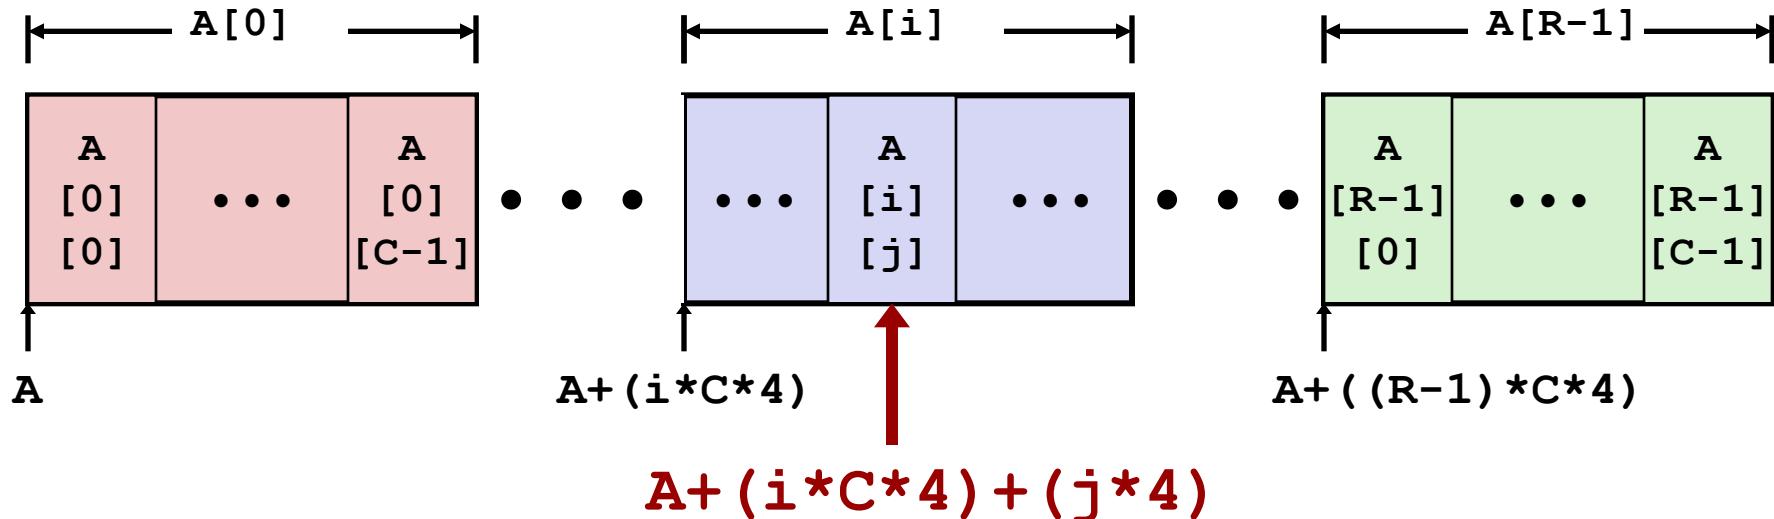

- Computes and returns address
- Compute as `pgh + 4*(index+4*index)`

Nested Array Element Access

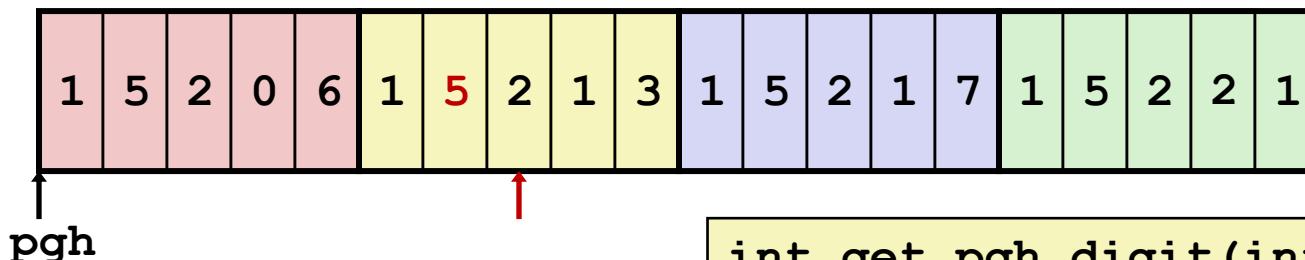

■ Array Elements

- $A[i][j]$ is element of type T , which requires K bytes
- Address $A + i * (C * K) + j * K$
 $= A + (i * C + j) * K$

`int A[R][C];`

Nested Array Element Access Code

```
int get_pgh_digit(int index, int dig)
{
    return pgh[index][dig];
}
```

```
leaq (%rdi,%rdi,4), %rax      # 5*index
addl %rax, %rsi                # 5*index+dig
movl pgh(,%rsi,4), %eax       # M[pgh + 4*(5*index+dig)]
```

■ Array Elements

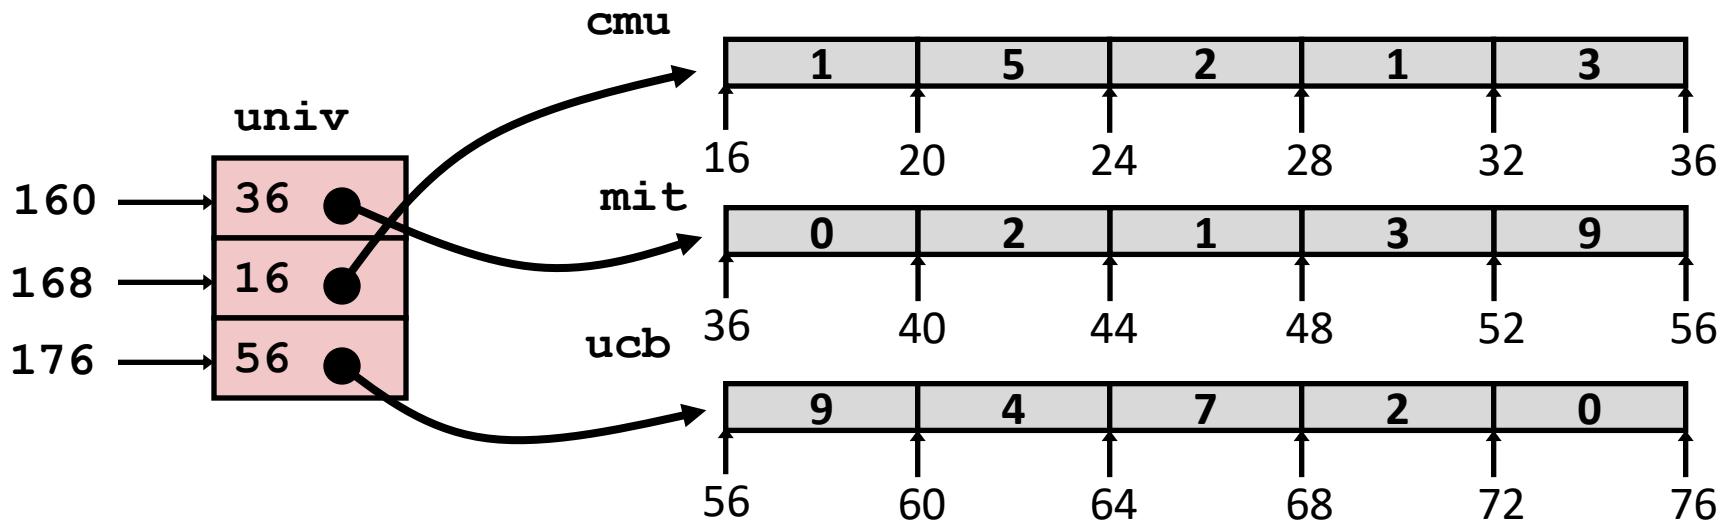

- `pgh[index][dig]` is `int`
- Address: $\text{pgh} + 20*\text{index} + 4*\text{dig}$
 $= \text{pgh} + 4*(5*\text{index} + \text{dig})$

Multi-Level Array Example

```
zip_dig cmu = { 1, 5, 2, 1, 3 };
zip_dig mit = { 0, 2, 1, 3, 9 };
zip_dig ucb = { 9, 4, 7, 2, 0 };
```

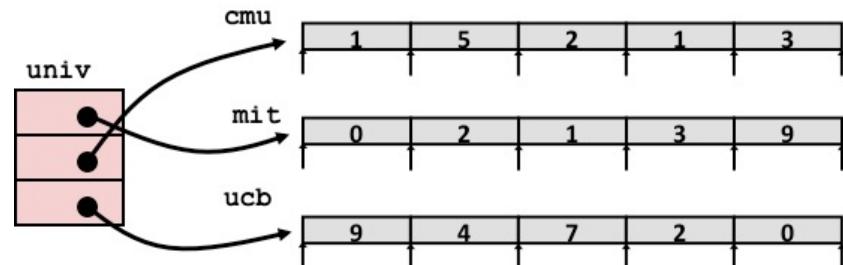

```
#define UCOUNT 3
int *univ[UCOUNT] = {mit, cmu, ucb};
```

- Variable **univ** denotes array of 3 elements
- Each element is a pointer
 - 8 bytes
- Each pointer points to array of int's

Element Access in Multi-Level Array

```
int get_univ_digit
    (size_t index, size_t digit)
{
    return univ[index][digit];
}
```

```
salq    $2, %rsi          # 4*digit
addq    univ(%rdi,8), %rsi # p = univ[index] + 4*digit
movl    (%rsi), %eax      # return *p
ret
```

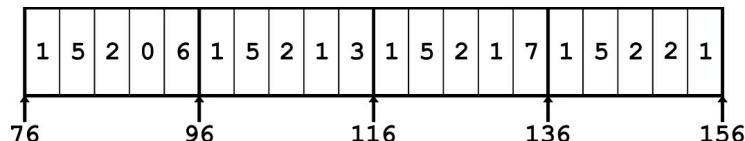

■ Computation

- Element access **Mem[Mem[univ+8*index]+4*digit]**
- Must do two memory reads
 - First get pointer to row array
 - Then access element within array

Array Element Accesses

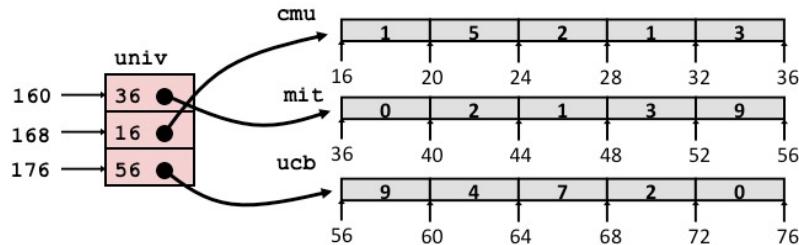

Nested array

```
int get_pgh_digit
    (size_t index, size_t digit)
{
    return pgh[index][digit];
}
```

Multi-level array

```
int get_univ_digit
    (size_t index, size_t digit)
{
    return univ[index][digit];
}
```

Accesses looks similar in C, but address computations very different:

`Mem[pgh+20*index+4*digit]`

`Mem[Mem[univ+8*index]+4*digit]`

$N \times N$ Matrix Code

■ Fixed dimensions

- Know value of N at compile time

```
#define N 16
typedef int fix_matrix[N][N];
/* Get element A[i][j] */
int fix_ele(fix_matrix A,
            size_t i, size_t j)
{
    return A[i][j];
}
```

■ Variable dimensions, explicit indexing

- Traditional way to implement dynamic arrays

```
#define IDX(n, i, j) ((i)*(n)+(j))
/* Get element A[i][j] */
int vec_ele(size_t n, int *A,
            size_t i, size_t j)
{
    return A[IDX(n,i,j)];
}
```

■ Variable dimensions, implicit indexing

- Not in K&R; added to language in 1999

```
/* Get element A[i][j] */
int var_ele(size_t n, int A[n][n],
            size_t i, size_t j) {
    return A[i][j];
}
```

16 X 16 Matrix Access

■ Array Elements

- `int A[16][16];`
- Address `A + i * (C * K) + j * K`
- $C = 16, K = 4$

```
/* Get element A[i][j] */  
int fix_ele(fix_matrix A, size_t i, size_t j) {  
    return A[i][j];  
}
```

```
# A in %rdi, i in %rsi, j in %rdx  
salq    $6, %rsi          # 64*i  
addq    %rsi, %rdi        # A + 64*i  
movl    (%rdi,%rdx,4), %eax # Mem[A + 64*i + 4*j]  
ret
```

$n \times n$ Matrix Access

■ Array Elements

- `size_t n;`
- `int A[n][n];`
- Address `A + i * (C * K) + j * K`
- $C = n, K = 4$
- Must perform integer multiplication

```
/* Get element A[i][j] */
int var_ele(size_t n, int A[n][n], size_t i, size_t j)
{
    return A[i][j];
}
```

```
# n in %rdi, A in %rsi, i in %rdx, j in %rcx
imulq    %rdx, %rdi          # n*i
leaq     (%rsi,%rdi,4), %rax # A + 4*n*i
movl     (%rax,%rcx,4), %eax # Mem[A + 4*n*i + 4*j]
ret
```

Example: Array Access

```
#include <stdio.h>

#define ZLEN 5
#define PCOUNT 4

typedef int zip_dig[ZLEN];

int main(int argc, char** argv) {
    zip_dig pgm =
        {{1, 5, 2, 0, 6},
         {1, 5, 2, 1, 3 },
         {1, 5, 2, 1, 7 },
         {1, 5, 2, 2, 1 }};

    int *linear_zip = (int *) pgm;
    int *zip2 = (int *) pgm[2];
    int result =
        pgm[0][0] +
        linear_zip[7] +
        *(linear_zip + 8) +
        zip2[1];
    printf("result: %d\n", result);
    return 0;
}
```

```
linux> ./array
```

Example: Array Access

```
#include <stdio.h>

#define ZLEN 5
#define PCOUNT 4

typedef int zip_dig[ZLEN];

int main(int argc, char** argv) {
    zip_dig pgm[PCOUNT] =
        {{1, 5, 2, 0, 6},
         {1, 5, 2, 1, 3},
         {1, 5, 2, 1, 7},
         {1, 5, 2, 2, 1}};

    int *linear_zip = (int *) pgm;
    int *zip2 = (int *) pgm[2];
    int result =
        pgm[0][0] +
        linear_zip[7] +
        *(linear_zip + 8) +
        zip2[1];
    printf("result: %d\n", result);
    return 0;
}
```

```
linux> ./array
result: 9
```

Quiz

<https://canvas.cmu.edu/courses/28101/quizzes/77023>

Today

■ Arrays

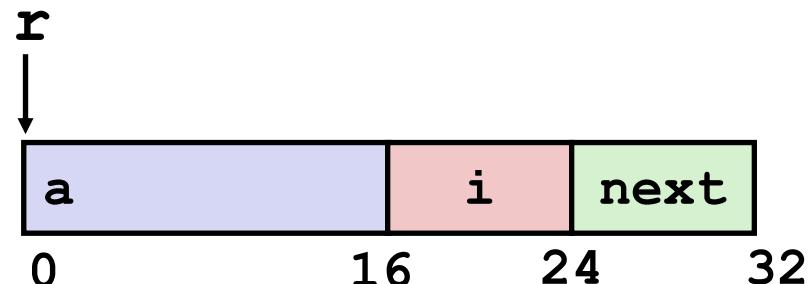

- One-dimensional
- Multi-dimensional (nested)
- Multi-level

■ Structures

- Allocation
- Access
- Alignment

Structure Representation

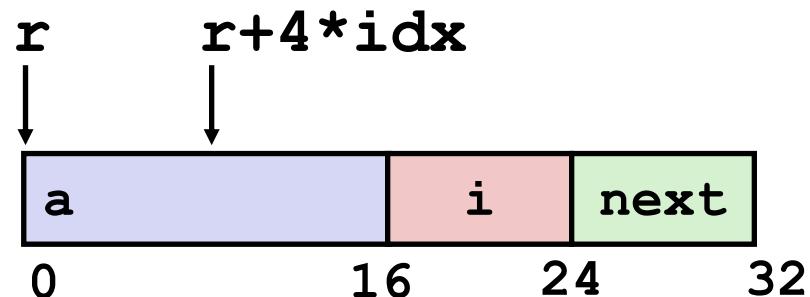

```
struct rec {  
    int a[4];  
    size_t i;  
    struct rec *next;  
};
```

- Structure represented as block of memory
 - Big enough to hold all the fields
- Fields ordered according to declaration
 - Even if another ordering could be more compact
- Compiler determines overall size + positions of fields
 - In assembly, we see only offsets, not field names

Generating Pointer to Structure Member

```
struct rec {
    int a[4];
    size_t i;
    struct rec *next;
};
```

■ Generating Pointer to Array Element

- Offset of each structure member determined at compile time
- Compute as `r + 4*idx`

```
int *get_ap
(struct rec *r, size_t idx)
{
    return &r->a[idx];
}
```

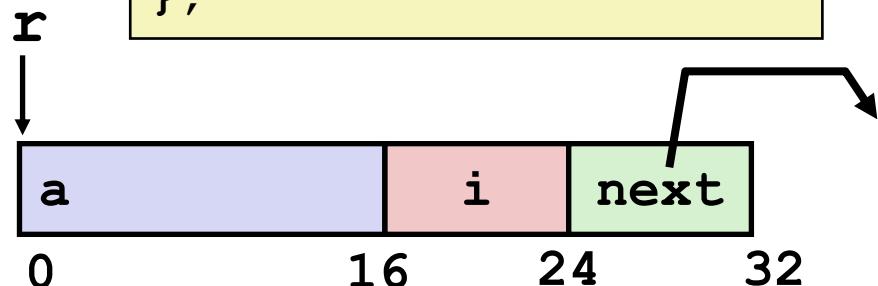

```
# r in %rdi, idx in %rsi
leaq (%rdi,%rsi,4), %rax
ret
```

Following Linked List #1

■ C Code

```
long length(struct rec*r) {
    long len = 0L;
    while (r) {
        len++;
        r = r->next;
    }
    return len;
}
```

```
struct rec {
    int a[4];
    size_t i;
    struct rec *next;
};
```

Register	Value
%rdi	r
%rax	len

■ Loop assembly code

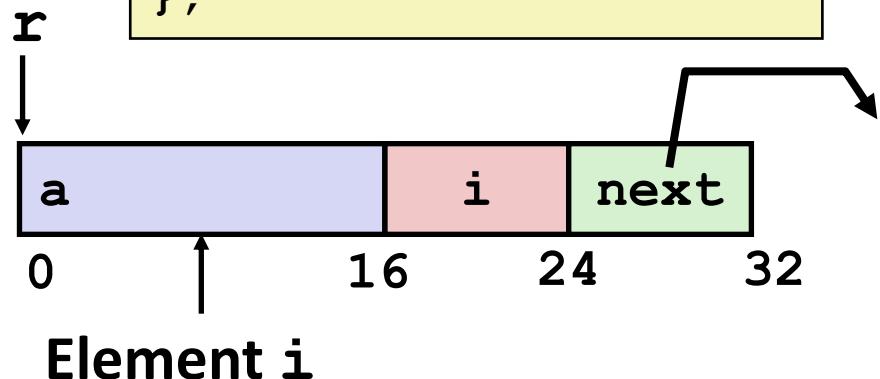

.L11:	# loop:
addq \$1, %rax	# len ++
movq 24(%rdi), %rdi	# r = Mem[r+24]
testq %rdi, %rdi	# Test r
jne .L11	# If != 0, goto loop

Following Linked List #2

■ C Code

```
void set_val
    (struct rec *r, int val)
{
    while (r) {
        size_t i = r->i;
        // No bounds check
        r->a[r->i] = val;
        r = r->next;
    }
}
```

```
struct rec {
    int a[4];
    size_t i;
    struct rec *next;
};
```

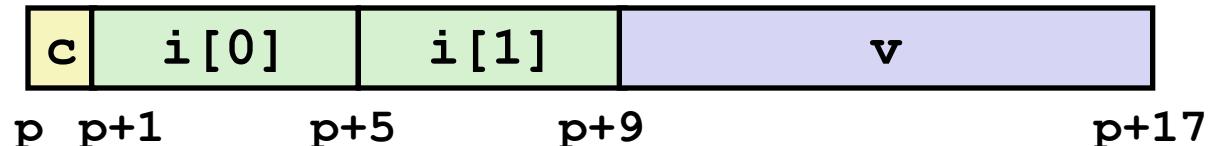

Element i

Register	Value
%rdi	r
%rsi	val

.L11:	# loop:
movq 16(%rdi), %rax	# i = Mem[r+16]
movl %esi, (%rdi,%rax,4)	# Mem[r+4*i] = val
movq 24(%rdi), %rdi	# r = Mem[r+24]
testq %rdi, %rdi	# Test r
jne .L11	# if !=0 goto loop

Structures & Alignment

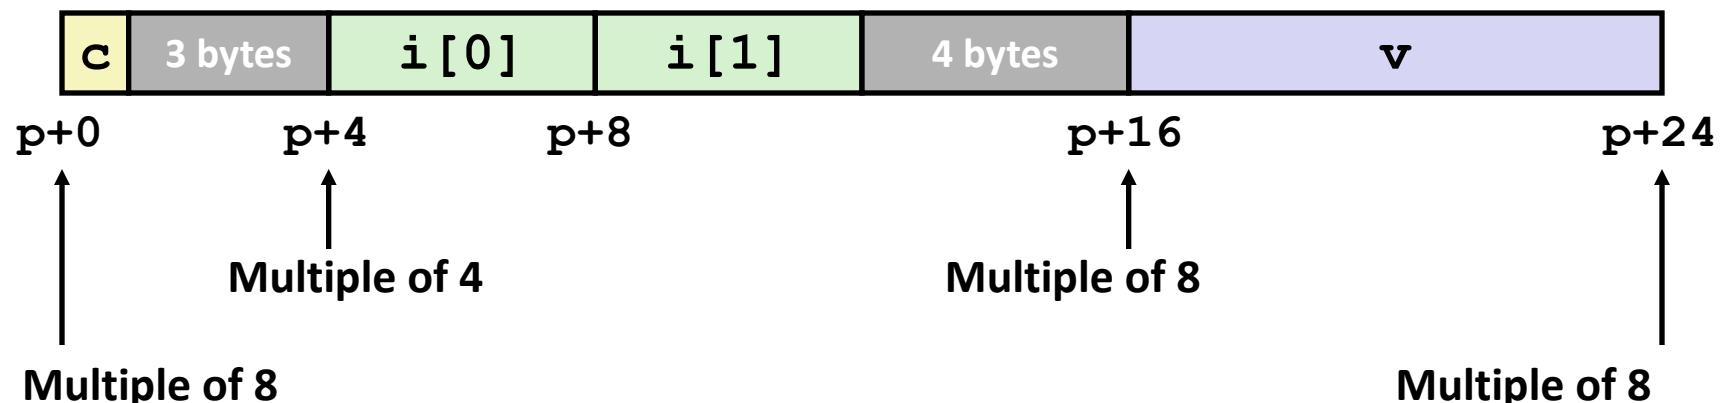

■ Unaligned Data

```
struct S1 {  
    char c;  
    int i[2];  
    double v;  
} *p;
```

■ Aligned Data

- Primitive data type requires B bytes implies Address must be multiple of B

Alignment Principles

■ Aligned Data

- Primitive data type requires B bytes
- Address must be multiple of B
- Required on some machines; advised on x86-64

■ Motivation for Aligning Data

- Memory accessed by (aligned) chunks of 4 or 8 bytes (system dependent)
 - Inefficient to load or store datum that spans cache lines (64 bytes).
Intel states should avoid crossing 16 byte boundaries.

[Cache lines will be discussed in Lecture 10.]

- Virtual memory trickier when datum spans 2 pages (4 KB pages)
[Virtual memory pages will be discussed in Lecture 17.]

■ Compiler

- Inserts gaps in structure to ensure correct alignment of fields

Specific Cases of Alignment (x86-64)

- **1 byte: `char`, ...**
 - no restrictions on address
- **2 bytes: `short`, ...**
 - lowest 1 bit of address must be 0_2
- **4 bytes: `int`, `float`, ...**
 - lowest 2 bits of address must be 00_2
- **8 bytes: `double`, `long`, `char *`, ...**
 - lowest 3 bits of address must be 000_2

Satisfying Alignment with Structures

■ Within structure:

- Must satisfy each element's alignment requirement

■ Overall structure placement

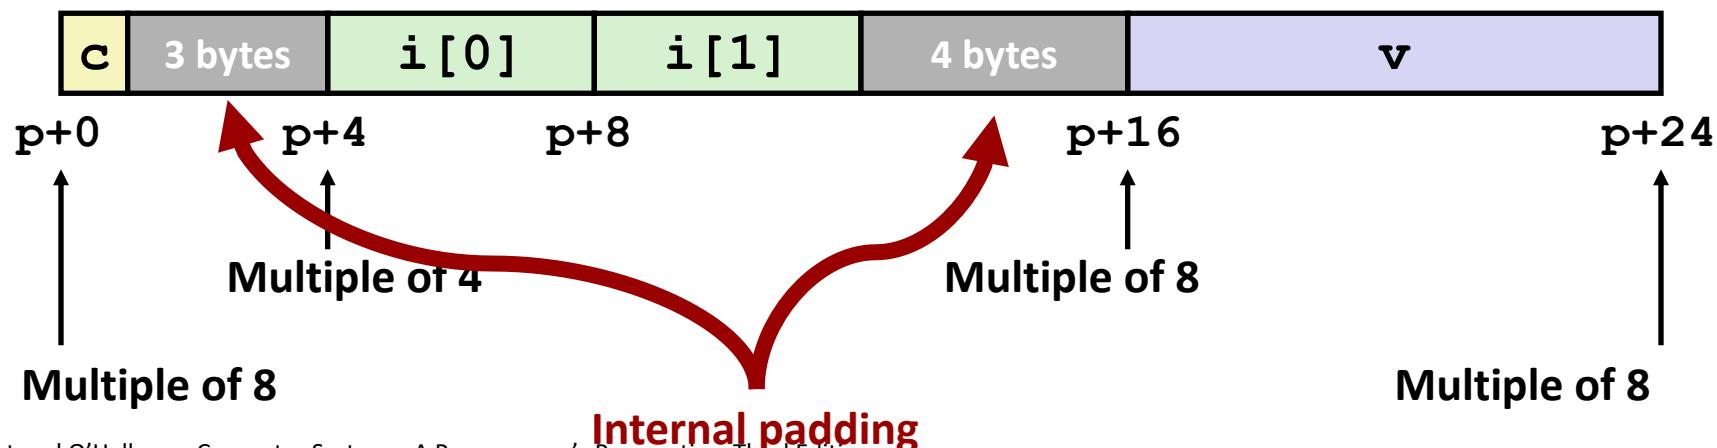

- Each structure has alignment requirement K
 - $K = \text{Largest alignment of any element}$
- Initial address & structure length must be multiples of K

■ Example:

- $K = 8$, due to **double** element

NOTE: $K < \text{sizeof}(\text{struct S1})$

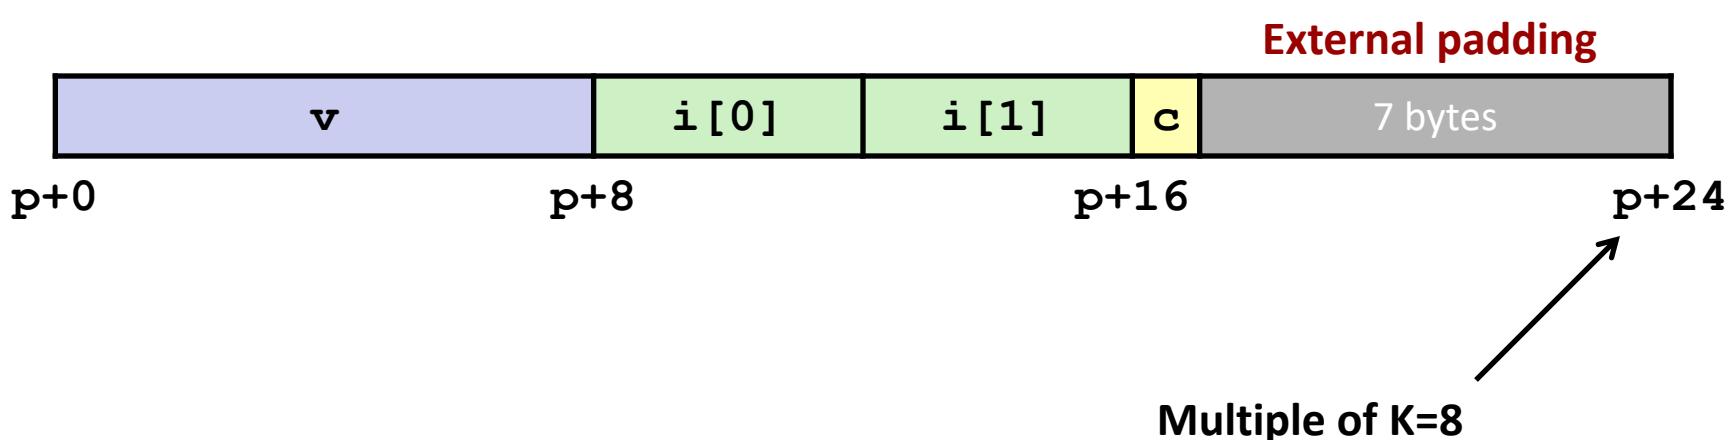

```
struct S1 {
    char c;
    int i[2];
    double v;
} *p;
```

Meeting Overall Alignment Requirement

- For largest alignment requirement K
- Overall structure must be multiple of K

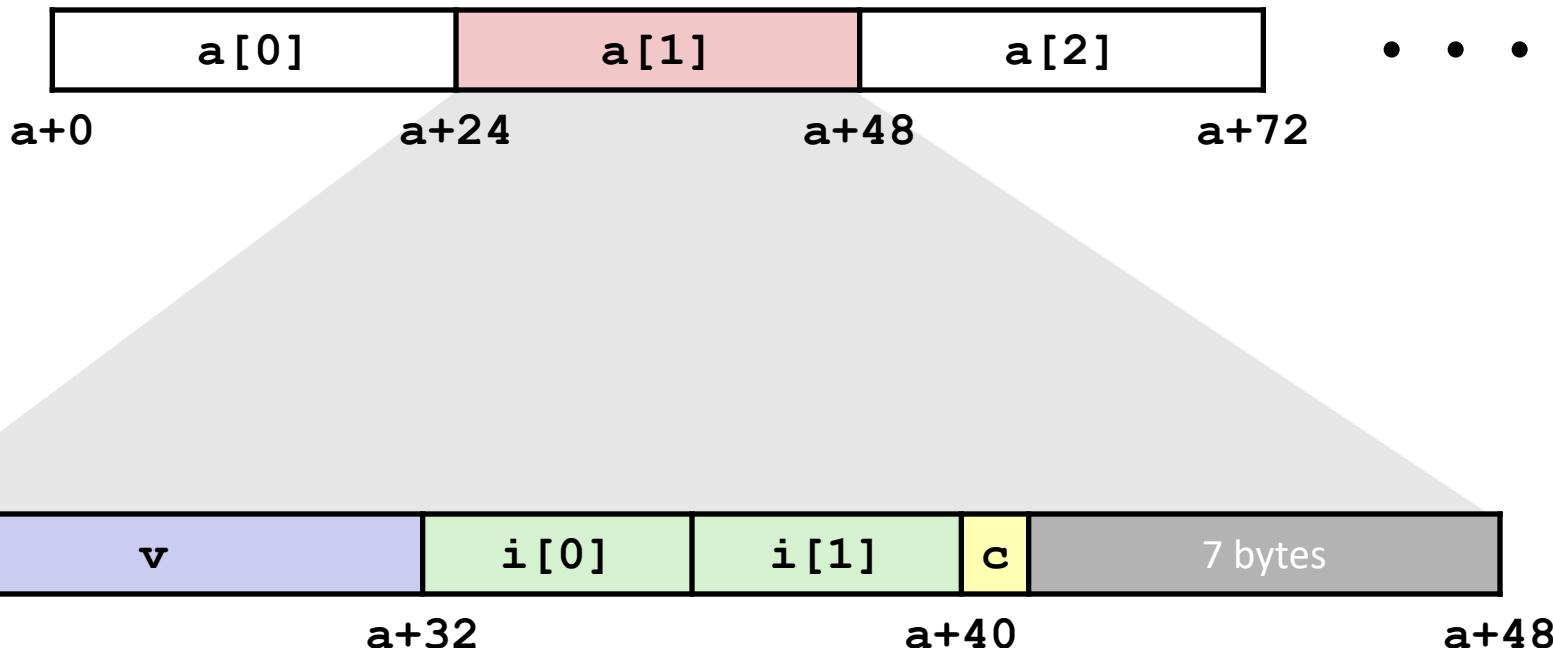

```
struct s2 {  
    double v;  
    int i[2];  
    char c;  
} *p;
```

Arrays of Structures

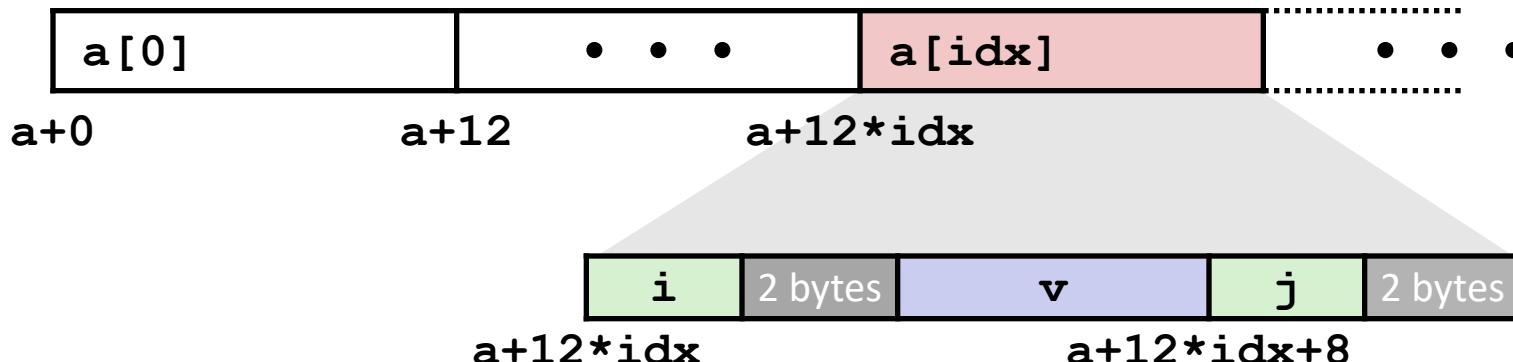

- No padding in between array elements
- Overall structure length multiple of K
- Satisfy alignment requirement for every element

```
struct S2 {  
    double v;  
    int i[2];  
    char c;  
} a[10];
```

Accessing Array Elements

- Compute array offset $12 * \text{idx}$
 - `sizeof(S3)`, including alignment spacers
- Element `j` is at offset 8 within structure
- Assembler gives offset `a+8`
 - Resolved during linking

```
short get_j(int idx)
{
    return a[idx].j;
}
```

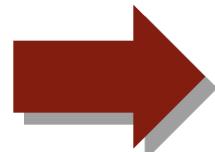

```
# %rdi = idx
leaq (%rdi,%rdi,2),%rax # 3*idx
movzwl a+8(%rax,4),%eax
```

```
struct S3 {
    short i;
    float v;
    short j;
} a[10];
```

Saving Space

- Put large data types first

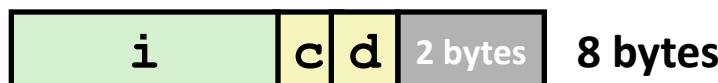

```
struct S4 {  
    char c;  
    int i;  
    char d;  
} *p;
```

```
struct S5 {  
    int i;  
    char c;  
    char d;  
} *p;
```

- Effect (largest alignment requirement K=4)

Today

■ Arrays

- One-dimensional
- Multi-dimensional (nested)
- Multi-level

■ Structures

- Allocation
- Access
- Alignment

Summary

■ Arrays

- Elements packed into contiguous region of memory
- Use index arithmetic to locate individual elements

■ Structures

- Elements packed into single region of memory
- Access using offsets determined by compiler
- Possible require internal and external padding to ensure alignment

■ Combinations

- Can nest structure and array code arbitrarily
