Malloc Bootcamp

Adithi, Anja, Eugene

June 28, 2020

Agenda

- Conceptual Overview
 - Explicit List
 - Segregated list
 - Splitting, coalescing
 - Hints on hints
- Advanced debugging with GDB
 - Fun GDB tricks
- Writing a good heap checker
- Appendix

Conceptual Outline

Me: *recompiles code I know damn well I didn't change*

code breaks

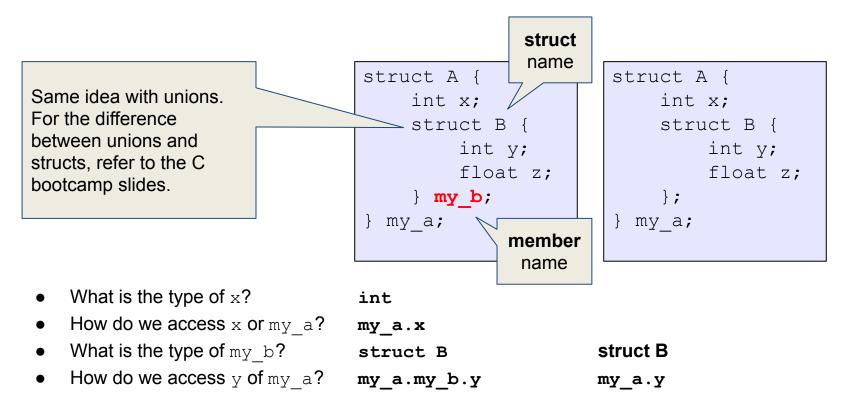

Also me:

Dynamic Memory Allocation

- Used when
 - we don't know at compile-time how much memory we will need
 - when a particular chunk of memory is not needed for the entire run
 - Iets us reuse that memory for storing other things
- Important terms:
 - malloc/calloc/realloc/free
 - mem_sbrk
 - payload
 - fragmentation (external vs internal)
 - Splitting / coalescing

Anonymous Structs/Unions

/** @brief Represents the header and payload of one block in the heap */ typedef struct block { /** @brief Header contains size + allocation flag */ word t header; /** * @brief A pointer to the block payload. * TODO: feel free to delete this comment once you've read it carefully. * We don't know what the size of the payload will be, so we will declare * it as a zero-length array, which is a GCC compiler extension. This will * allow us to obtain a pointer to the start of the payload. * WARNING: A zero-length array must be the last element in a struct, so * there should not be any struct fields after it. For this lab, we will * allow you to include a zero-length array in a union, as long as the * union is the last field in its containing struct. However. this is * compiler-specific behavior and should be avoided in general. * * WARNING: DO NOT cast this pointer to/from other types! Instead, you * should use a union to alias this zero-length array with another struct, * in order to store additional types of data in the payload memory. */ char payload[0]; /* * TODO: delete or replace this comment once you've thought about it. * Why can't we declare the block footer here as part of the struct? * Why do we even have footers -- will the code work fine without them? * which functions actually use the data contained in footers? */ block t;

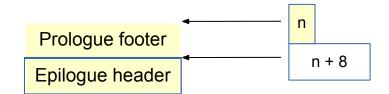

Zero-Length Arrays

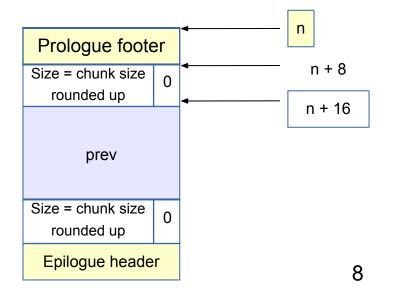

```
struct line {
    int length;
    char contents[0];
};
int main() {
    struct line my_line;
    printf("sizeof(contents) = %zu\n", sizeof(L.contents)); // 0
    printf("sizeof(struct line) = %zu\n", sizeof(struct line)); // 4
```

- It's a GCC extension not part of the C specification!
- Must be at the end of a struct / union
- It simply allows us to represent variable-length structures
- **sizeof** on a zero-length array returns zero

mm_init

- Why prologue footer and epilogue header?
- Payload must be 16-byte aligned
- But, the size of payload doesn't have to be a multiple of 16 - just the block does!
- Things malloc'd must be within the prologue and epilogue

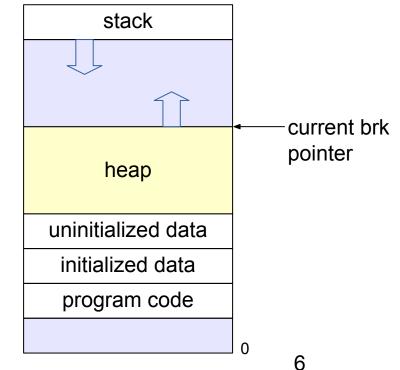

If We Can't Find a Usable Free Block

- Assume an implicit list implementation
- Need to extend the heap
 - mem_sbrk()
 - sbrk(num_bytes) allocates space and returns pointer to start
 - sbrk(0) returns a pointer to the end of the current heap
- For speed, extend the heap by a little

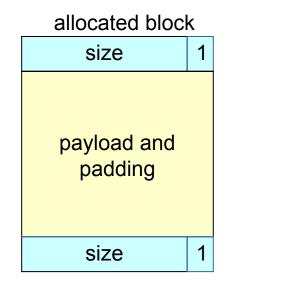

more than you need immediately

- use what you need out of the new space, add the rest as a free block
- What are some tradeoffs you can make?

Tracking Blocks: Explicit List

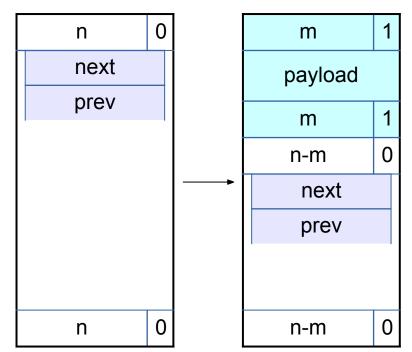

- Maintain a list of *free* blocks instead of *all* blocks •
 - means we need to store forward/backward pointers, not just sizes
 - we only track free blocks, so we can store the pointers in the payload area!
 - need to store size at end of block too, for coalescing

Splitting a Block

- If the block we find is larger than we need, split it and leave the remainder for a future allocation
 - explicit lists: correct previous and next pointers
 - Segregated lists: same as explicit
- When would we not split a block?

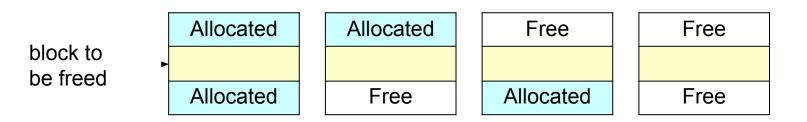

Coalescing Memory

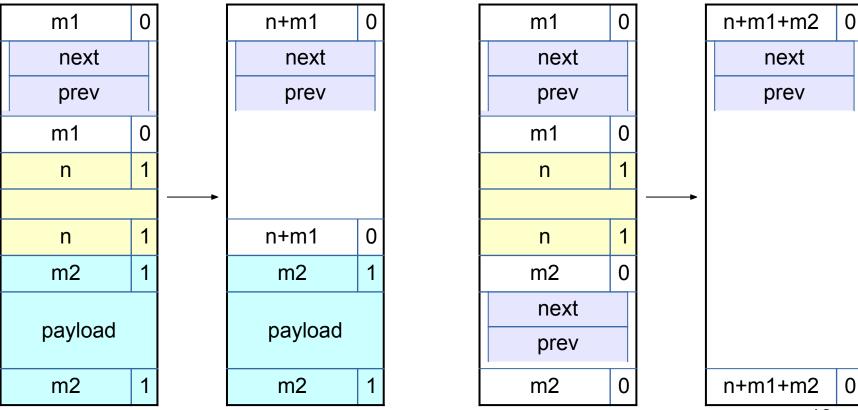

Combine adjacent blocks if both are free

 explicit lists: look forward and backward in the heap, using block sizes, not next/prev

Coalescing Memory

Design Considerations

- Finding a matching free block
 - First fit vs. next fit vs. best fit vs. "good enough" fit
 - continue searching for a closer fit after finding a big-enough free block?
- Free block ordering
 - LIFO, FIFO, or address-ordered?
- When to coalesce
 - while freeing a block or while searching for free memory?
- How much memory to request with sbrk()
 - larger requests save time in system calls but increase maximum memory use

Hints on hints

For the final, you must greatly increase the utilization and keep a high throughput.

- Reducing external fragmentation requires achieving something closer to best-fit allocated
 - Using a better fit algorithm
 - Combine with a better data structure that lets you run more complex algorithms
- Reducing internal fragmentation requires reducing data structure overhead and using a 'good' free block

Segregated Lists

- Multiple explicit lists where the free blocks are of a certain size range
- Increases throughput and raises probability of choosing a better-sized block
- Need to decide what size classes (only 128 bytes of stack space)
 - Diminishing returns
 - What do you do if you can't find something in the current size class?
- RootSizeClass1 -> free-block 1 -> free-block 2 -> free-block 3 ->
- RootSizeClass2 -> free-block 1 -> free-block 2 -> free-block 3 -> ...
- RootSizeClass3 -> free-block 1 -> free-block 2 -> free-block 3 -> ...

Modularity and Design

- Now you need to have more than one list
 - List operations are the same for all lists
 - Insert
 - Remove
 - \circ $\,$ Deciding which size class a block should go into
 - 14 if statements :(
 - A small **const** array of sizes + a loop :)
- It would be quite painful to maintain copy-pasted code
 - Abstractions are nice it's what CS is all about!

Modularity and Design

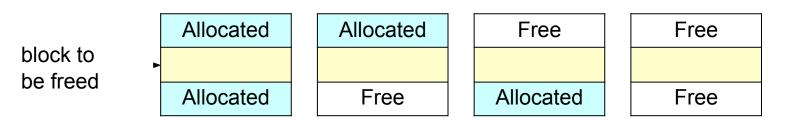

- Make sure you have modular, extensible code
 - It will save you a lot of time spent debugging and style points
 - It will make you happy when you come back to your code
 - In 6 days when you start the final submission
 - Or in 6 hours if you're missing sleep please get some rest!
 - It will make it easier to explain to students when you become a TA later :)
- Labs in this course are NOT meant to be done in one sitting
- Labs in this course are NOT meant to be done in 2-3 nights
- Plan ahead, leave plenty of time for **design**
 - Measure twice, cut once
- Take a break between sittings
 - Your brain can keep working subconsciously
 - Leave time for "aha!" moments

Coalescing Memory

Combine adjacent blocks if both are free

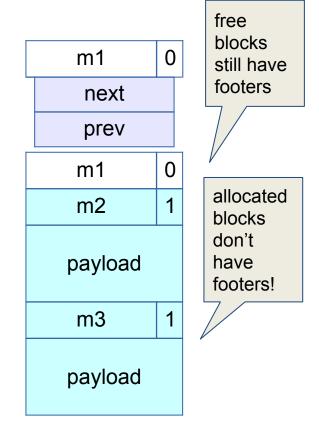

- **segregated lists**: look forward and back using block sizes, then
 - Use the size of the coalesced block to determine the proper list
 - What else might you need to do to maintain your seglists?
 - Insert into list using the insertion policy (LIFO, address-ordered, etc.)

Four cases:

Eliminate footers in allocated

- **DOCALS**es internal fragmentation (increase utilization)
 - Why do we need footers?
 - Coalescing blocks
 - What kind of blocks do we coalesce?
 - Do we need to know the size of a block if we're not going to coalesce it?
 - Based on that idea, can you design a method that helps you determine when to coalesce?
 - Hint: where could you store a little **bit** of extra information for each block?

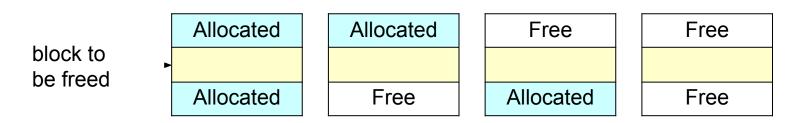

Coalescing Memory

Combine adjacent blocks if both are free

footerless: if free, obtain info from footer then use next/prev

• Four cases:

Decrease the minimum block size

- Reduces internal fragmentation (increase utilization)
- Currently, min block size is 32.
 - 8 byte header
 - 16 byte payload (or 2 8 byte pointers for free)
 - 8 byte footer
- If you just need to malloc(5), and the payload size is 16 bytes, you waste 11 bytes.
- Must manage free blocks that are too small to hold the pointers for a **doubly** linked free list

| header | block size | F |
|--------|----------------------------|-----|
| | potential payload space (1 | .6) |
| footer | block size | F |

| neader | block size | Α |
|--------|--------------------|---|
| | actual payload (5) | |
| | bytes wasted (11) | |
| footer | block size | Α |

9 bytes are wasted! How can we prevent this?

Debugging: GDB & The Almighty Heap Checker

When your scattered print statements don't reveal where the error is

What's better than printf? Using GDB

- Use GDB to determine where segfaults happen!
- gdb mdriver will open the malloc driver in gdb
 - Type run and your program will run until it hits the segfault!
- **step/next** (abbrev. **s/n**) step to the next line of code
 - **next** steps over function calls
- **finish** continue execution until end of current function, then break
- print <expr> (abbrev. p) Prints any C-like expression (including results of function calls!)
 - Consider writing a heap printing function to use in GDB!
- **x <expr>** Evaluate <expr> to obtain address, then examine memory at that address
 - **x /a <expr>** formats as address
 - See **help p** and **help x** for information about more formats

Using GDB - Fun with frames

backtrace - (abbrev. **bt**) print call stack up until current function

backtrace full - (abbrev. **bt full**) print local variables in each frame

(gdb) backtrace

- #0 find_fit (...)
- #1 mm_malloc (...)
- #2 0x0000000000403352 in eval_mm_valid
- (...) #3 run_tests (...)
- #4 0x0000000000403c39 in main (...)
- frame 1 (abbrev. f 1) switch to mm_malloc's stack frame
 Good for inspecting local variables of calling functions

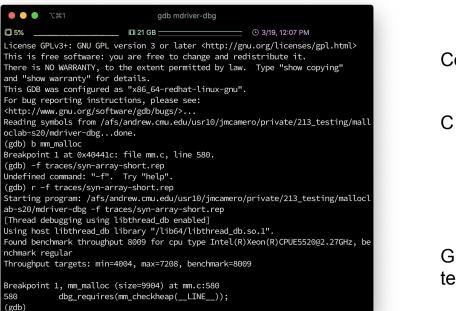

Using GDB - Setting breakpoints/watchpoints

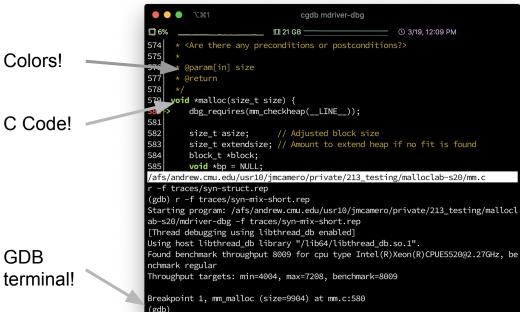

break mm_checkheap - (abbrev. b) break on "mm_checkheap()"

- **b mm.c:25** break on line 25 of file "mm.c" **very useful!**
- b find_fit if size == 24 break on function "find_fit()" if the local variable "size" is equal to 24 "conditional breakpoint"
- watch heap_listp (abbrev. w) break if value of "heap_listp" changes -"watchpoint"
- w block == 0x80000010 break if "block" is equal to this value
- w *0x15213 watch for changes at memory location 0x15213
 - Can be *very* slow
- rwatch <thing> stop on reading a memory location
- awatch <thing> stop on any memory access

What's better than GDB? Using CGDB!

- CGDB is just like GDB
 - but with COLOR and SOURCE_CODE
- Breaking at mm_malloc in GDB vs CGDB

Using CGDB

• Initializes the same as GDB

 Just write cgdb mdriver-dbg instead of gdb mdriver-dbg

Source and gdb windows

- To go from gdb (default) to source press esc (just like normal mode in vim!!!!)
- to go from source to gdb press i (just like insert mode in vim!!!!)

cadb mdriver-dba 17% 1 21 GB ① 3/19, 12:16 PM 591 592 593 // Ignore spurious request **if** (size == 0) { 594 dbg_ensures(mm_checkheap(__LINE__)); 595 596 597 598 599 return bp; // Adjust block size to include overhead and to meet alignment requirem asize = round_up(size + dsize, dsize); 600 601 602 -> // Search the free list for a fit block = find_fit(asize); 603 604 // If no fit is found, request more memory, and then and place the bloc 605 606 if (block == NULL) { // Always request at least chunksize 607 extendsize = max(asize, chunksize); 608 block = extend_heap(extendsize); 609 // extend_heap returns an error 610 if (block == NULL) { 611 return bp; 612 /afs/andrew.cmu.edu/usr10/jmcamero/private/213_testing/malloclab-s20/mm.c r -f traces/syn-string-scaled.rep -f traces/syn-string-short.rep -f traces/syn-string.rep -f traces/syn-struct-scaled.rep r -f traces/syn-struct-short.rep r -f traces/syn-struct.rep (gdb) r -f traces/syn-mix-short.rep Starting program: /afs/andrew.cmu.edu/usr10/jmcamero/private/213_testing/mallocl ab-s20/mdriver-dbg -f traces/syn-mix-short.rep [Thread debugging using libthread_db enabled] Using host libthread_db library "/lib64/libthread_db.so.1". Source

Source Mode

• Benefits

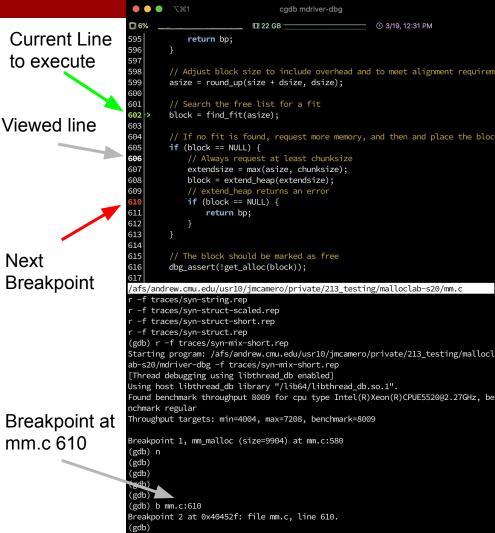

- see breakpoints in the file
- reread code while debugging
- review what is coming

• Usage

- Very similar to vim!!
- j move down a line
- k move up a line
- :### jump to line ###
- /### search for ###
- Most other vim commands!

Notes

- Green line number is current line
- Red line number is breakpoint

CGDB Misc

- GDB mode functions exactly like normal GDB!
 - All the commands you know and love work the same!
- Shark machines use version 0.6.8
 - Means unfortunately no assembly viewer :(though that is not often needed.
- Website
 - <u>https://cgdb.github.io/</u>
- Documentation
 - o <u>https://cgdb.github.io/docs/cgdb.pdf</u>
 - Version 0.7.1

Heap Checker

- int mm_checkheap(int verbose);
- critical for debugging
 - write this function early!
 - update it when you change your implementation
 - check all heap invariants, make sure you haven't lost track of any part of your heap
 - check should pass if and only if the heap is truly well-formed
 - should only generate output if a problem is found, to avoid cluttering up your program's output
- meant to be correct, not efficient
- call before/after major operations when the heap should be well-formed

Heap Invariants (Non-Exhaustive)

Block level

What are some things which should always be true of every block in the heap?

Heap Invariants (Non-Exhaustive)

Block level

- header and footer match
- payload area is aligned, size is valid
- no contiguous free blocks unless you defer coalescing
- List level
 - What are some things which should always be true of every element of a free list?

Heap Invariants (Non-Exhaustive)

Block level

- header and footer match
- payload area is aligned, size is valid
- no contiguous free blocks unless you defer coalescing

List level

- next/prev pointers in consecutive free blocks are consistent
- no allocated blocks in free list, all free blocks are in the free list
- no cycles in free list unless you use a circular list
- each segregated list contains only blocks in the appropriate size class

Heap level

What are some things that should be true of the heap as a whole?

Heap Invariants (Non-Exhaustive) Block level

- header and footer match
- payload area is aligned, size is valid
- no contiguous free blocks unless you defer coalescing
- List level
 - next/prev pointers in consecutive free blocks are consistent
 - no allocated blocks in free list, all free blocks are in the free list
 - no cycles in free list unless you use a circular list
 - each segregated list contains only blocks in the appropriate size class
- Heap level
 - all blocks between heap boundaries, correct sentinel blocks (if used)

How to Ask for Help

- Be specific about what the problem is, and how to cause it
 - **BAD:** "My program segfaults."
 - GOOD: "I ran mdriver in gdb and it says that a segfault occurred due to an invalid next pointer, so I set a watchpoint on the segfaulting next pointer. How can I figure out what happened?"
 - **GOOD:** "My heap checker indicates that my segregated list has a block of the wrong size in it after performing a coalesce(). Why might that be the case?"
 - What sequence of events do you expect around the time of the error? What part of the sequence has already happened?
- Have you written your mm_checkheap function, and is it working?
 We WILL ask to see it!
- Use a rubber duck!

If You Get Stuck

Please read the writeup!

- CS:APP Chapter 9
- View lecture notes and course FAQ at

http://www.cs.cmu.edu/~213

- Office hours Sunday through Friday 5:30-9:30pm over Zoom. See pinned Piazza post!
- Post a private question on Piazza
- Obtain a rubber duck at

APPENDIX

Internal Fragmentation

Occurs when the *payload* is smaller than the block size

- due to alignment requirements
- due to management overhead
- as the result of a decision to use a larger-than-necessary block
- Depends on the current allocations, i.e. the pattern of *previous* requests

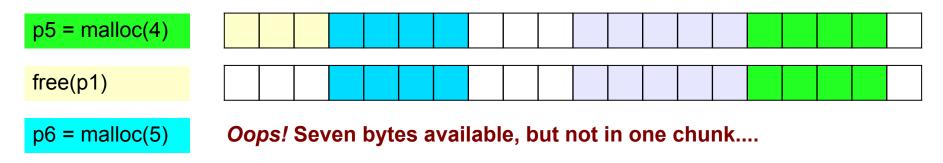

Internal Fragmentation

- Due to alignment requirements the allocator doesn't know how you'll be using the memory, so it has to use the strictest alignment:
 - void *m1 = malloc(13); void *m2 = malloc(11);
 - m1 and m2 both have to be aligned on 8-byte boundaries

External Fragmentation

- Occurs when the total free space is sufficient, but no single free block is large enough to satisfy the request
- Depends on the pattern of *future* requests
 - thus difficult to predict, and any measurement is at best an estimate
- Less critical to malloc traces than internal fragmentation

C: Pointer Arithmetic

- Adding an integer to a pointer is different from adding two integers
- The value of the integer is always multiplied by the size of the type that the pointer points at
- Example:
 - type_a *ptr = ...;
 - type_a *ptr2 = ptr + a;
- is really computing
 - ptr2 = ptr + (a * sizeof(type_a));
 - i.e. lea (ptr, a, sizeof(type_a)), ptr2
- Pointer arithmetic on void* is undefined (what's the size of a void?) 42

C: Pointer Arithmetic

int *ptr = (int*)0x152130; int *ptr2 = ptr + 1;

• char *ptr = (char*)0x152130; char *ptr2 = ptr + 1;

• char *ptr = (char*)0x152130; void *ptr2 = ptr + 1;

char *ptr = (char*)0x152130; char *p2 = ((char*)(((int*)ptr)+1));

C: Pointer Arithmetic

int *ptr = (int*)0x152130;

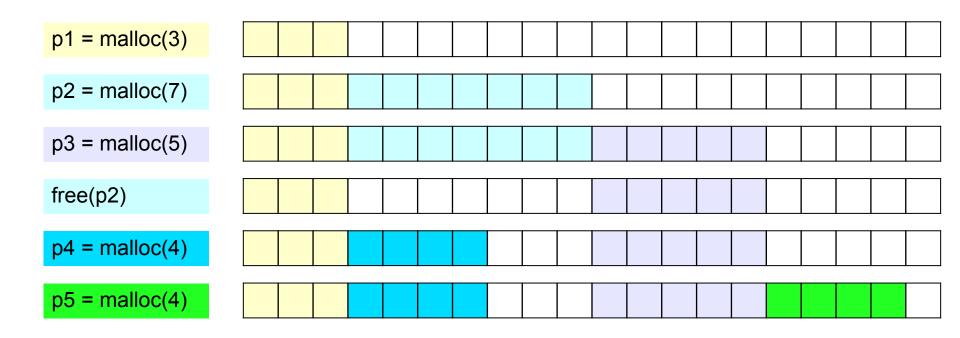

int *ptr2 = ptr + 1; // ptr2 is 0x152134

• char *ptr = (char*) 0x152130; char *ptr2 = ptr + 1; // ptr2 is 0x152131

• char *ptr = (char*)0x152130; void *ptr2 = ptr + 1; // ptr2 is still 0x152131

• char *ptr = (char*)0x152130; char *p2 = ((char*)(((int*)ptr)+1));// p2 is 0x152134

Dynamic Memory Allocation: Example

The Memory-Block Information Data Structurements:

- tells us where the blocks are, how big they are, and whether they are free
- must be able to update the data during calls to malloc and free
- need to be able to find the next free block which is a "good enough fit" for a given payload
- need to be able to quickly mark a block as free or allocated
- need to be able to detect when we run out of blocks
 - what do we do in that case?
- The only memory we have is what we're handing out
 - ...but not all of it needs to be payload! We can use part of it to store the block information.

Finding a Free Block

First Fit

- search from beginning, use first block that's big enough
- linear time in total number of blocks
- can cause small "splinters" at beginning of list

Next Fit

- start search from where previous search finished
- often faster than first fit, but some research suggests worse fragmentation

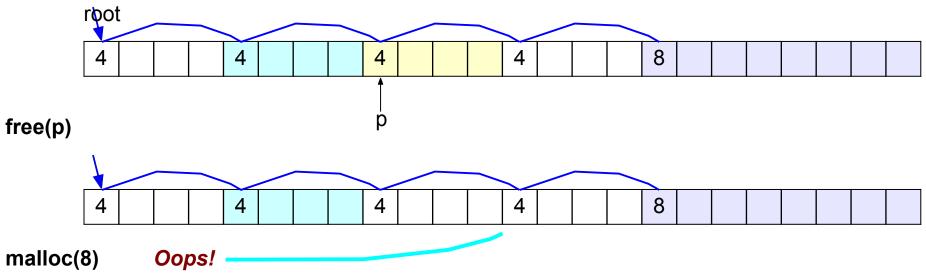

Best Fit

- search entire list, use smallest block that's big enough
- keeps fragments small (less wasted memory), but slower than first fit

Freeing Blocks

Simplest implementation is just clearing the "allocated" flag

but leads to external fragmentation

Insertion Policy

Where do you put a newly-freed block in the free list?

- LIFO (last-in-first-out) policy
 - add to the beginning of the free list
 - pro: simple and constant time (very fast)
 - block->next = freelist; freelist = block;
 - con: studies suggest fragmentation is worse
- Address-ordered policy
 - insert blocks so that free list blocks are always sorted by address addr(prev) < addr(curr) < addr(next)</p>
 - pro: lower fragmentation than LIFO
 - con: requires search

C: Pointer Casting

- Notation: (b*) a "casts" a to be of type b*
- Casting a pointer doesn't change the bits!
 - type_a *ptr_a=...; type_b *ptr_b=(type_b*)ptr_a; makes ptr_a and ptr_b contain identical bits
- But it does change the behavior when dereferencing
 - because we interpret the bits differently
- Can cast type_a* to long/unsigned long and back
 - pointers are really just 64-bit numbers
 - such casts are important for malloclab
 - but be careful this can easily lead to hard-to-find errors

Cycle Checking: Hare and Tortoise Algorithm

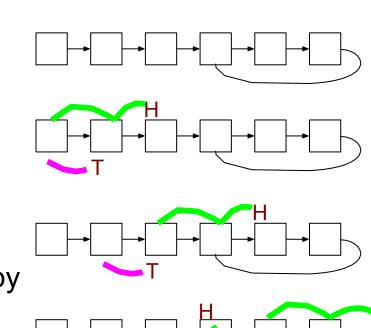

Н

Т

- This algorithm detects cycles in linked lists
- Set two pointers, called "hare" and "tortoise", to the beginning of the list
- During each iteration, move "hare" forward by two nodes, "tortoise" by one node
 - if "tortoise" reaches the end

of the list, there is no cycle

• if "tortoise" equals "hare", the list has a cycle

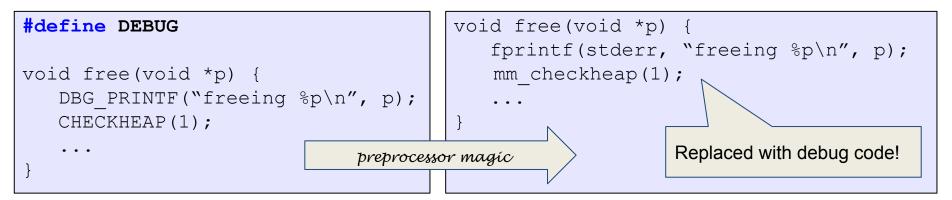

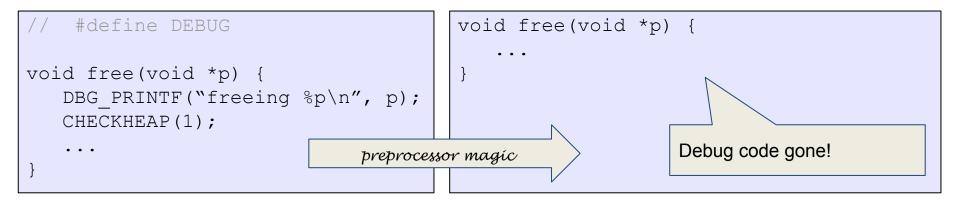

Debugging Tip: Using the Preprocessor

 Use conditional compilation with #if or #ifdef to easily turn debugging code on or off

```
#ifdef DEBUG
#define DBG PRINTF(...) fprintf(stderr, VA ARGS)
#define CHECKHEAP(verbose) mm checkheap(verbose)
#else
                               comment line below to disable debug code!
#define DBG PRINTF(...)
                            #define DEBUG
#define CHECKHEAP(verbose)
#endif /* DEBUG */
                            void free(void *p) {
                               DBG PRINTF("freeing %p\n", p);
                               CHECKHEAP(1);
                                . . .
```

Debugging Tip: Using the Preprocessor (contd)

Header Reduction

- Note: this is completely optional and generally discouraged due to its relative difficulty
 - Do NOT attempt unless you are satisfied with your implementation as-is
- When to use 8 or 4 byte header? (must support all possible block sizes)
- If 4 byte, how to ensure that payload is aligned?
- Arrange accordingly
- How to coalesce if 4 byte header block is followed by 8 byte header block?
- Store extra information in headers
