Review: Dynamic Memory Allocation

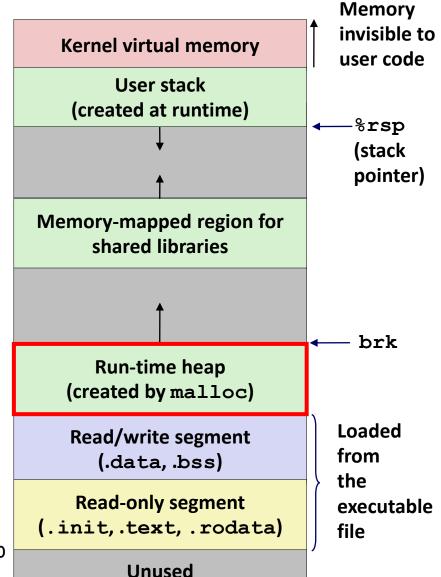

Application

Dynamic Memory Allocator

Heap

- Programmers use dynamic memory allocators (such as malloc) to acquire virtual memory (VM) at runtime
 - For data structures whose size is only known at runtime
- Dynamic memory allocators manage an area of process
 VM known as the heap

0x400000

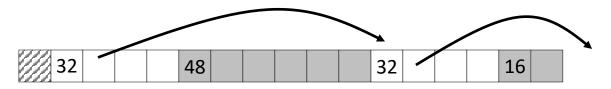

Review: Keeping Track of Free Blocks

■ Method 1: *Implicit list* using length—links all blocks

Need to tag each block as allocated/free

Method 2: Explicit list among the free blocks using pointers

Need space for pointers

- Method 3: Segregated free list
 - Different free lists for different size classes
- Method 4: *Blocks sorted by size*
 - Can use a balanced tree (e.g., Red-Black tree) with pointers within each free block, and the length used as a key

Review: Implicit Lists Summary

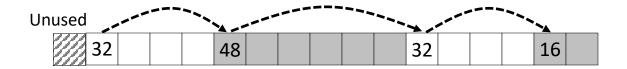

- Implementation: very simple
- Allocate cost:
 - linear time worst case
- Free cost:
 - constant time worst case
 - even with coalescing
- Memory Overhead:
 - Depends on placement policy
 - Strategies include first fit, next fit, and best fit
- Not used in practice for malloc/free because of lineartime allocation
 - used in many special purpose applications
- However, the concepts of splitting and boundary tag coalescing are general to all allocators

Today

- Explicit free lists
- Segregated free lists
- Memory-related perils and pitfalls

Keeping Track of Free Blocks

Method 1: Implicit list using length—links all blocks

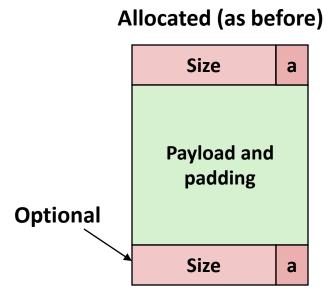

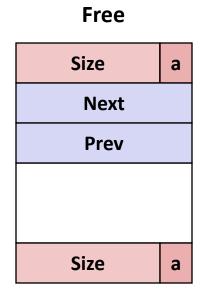

Method 2: Explicit list among the free blocks using pointers

- Method 3: Segregated free list
 - Different free lists for different size classes
- Method 4: *Blocks sorted by size*
 - Can use a balanced tree (e.g. Red-Black tree) with pointers within each free block, and the length used as a key

Explicit Free Lists

Maintain list(s) of free blocks, not all blocks

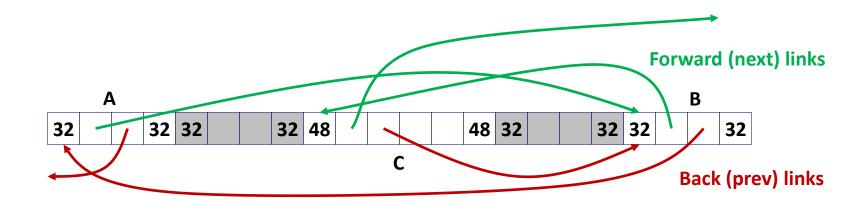

- Luckily we track only free blocks, so we can use payload area
- The "next" free block could be anywhere
 - So we need to store forward/back pointers, not just sizes
- Still need boundary tags for coalescing
 - To find adjacent blocks according to memory order

Explicit Free Lists

Logically:

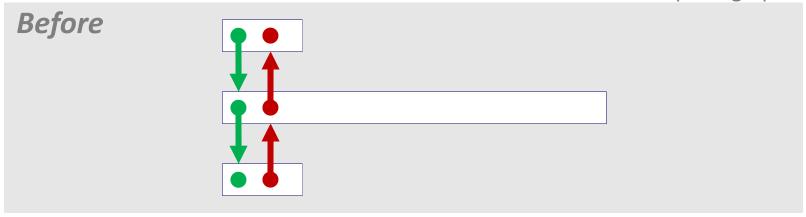

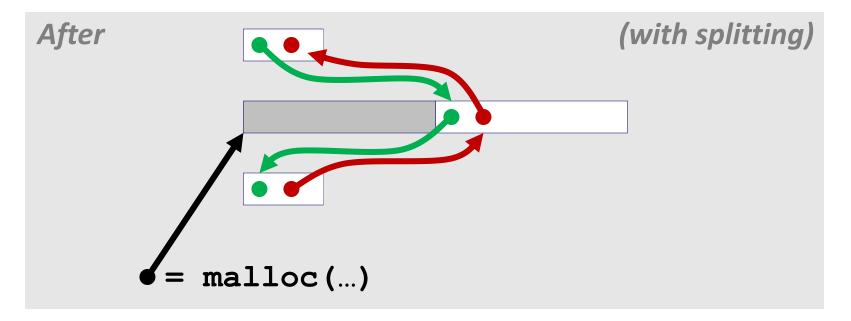

Physically: blocks can be in any order

Allocating From Explicit Free Lists

conceptual graphic

Freeing With Explicit Free Lists

Insertion policy: Where in the free list do you put a newly freed block?

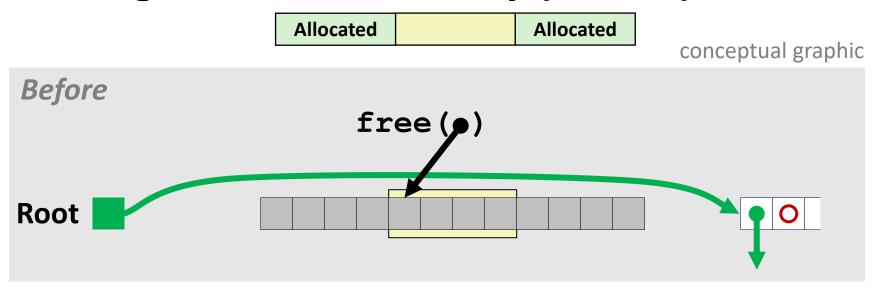

Unordered

- LIFO (last-in-first-out) policy
 - Insert freed block at the beginning of the free list
- FIFO (first-in-first-out) policy
 - Insert freed block at the end of the free list
- Pro: simple and constant time
- Con: studies suggest fragmentation is worse than address ordered

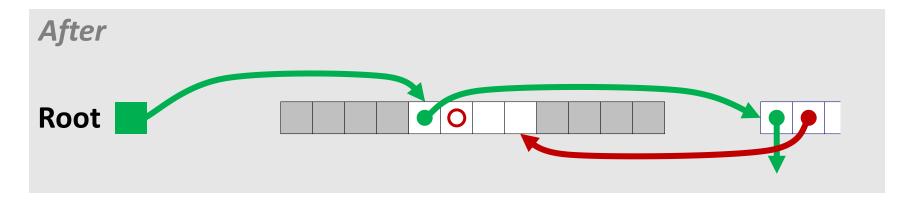

Address-ordered policy

- Insert freed blocks so that free list blocks are always in address order:
 addr(prev) < addr(curr) < addr(next)</p>
- Con: requires search
- Pro: studies suggest fragmentation is lower than LIFO/FIFO

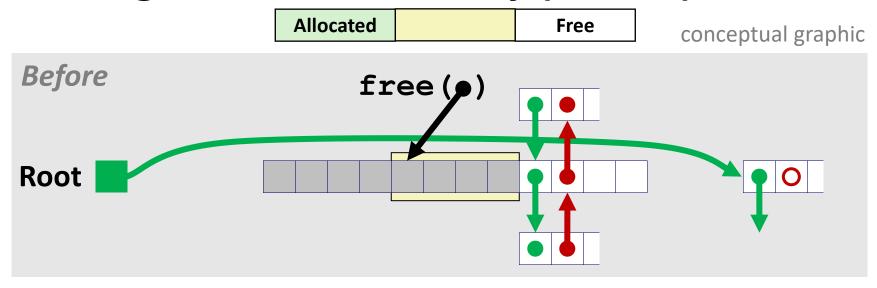

Freeing With a LIFO Policy (Case 1)

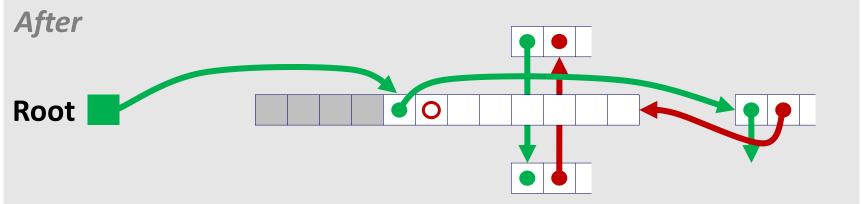

Insert the freed block at the root of the list

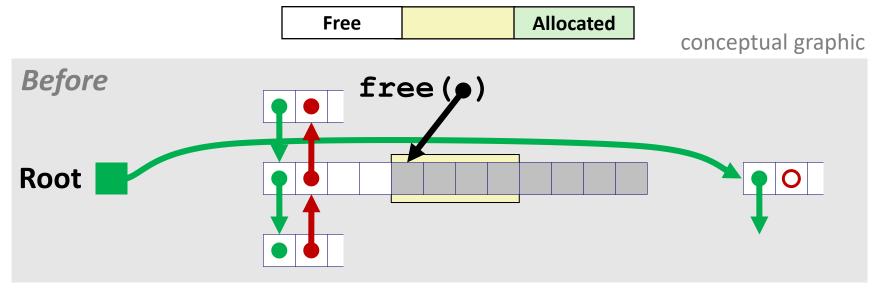

Freeing With a LIFO Policy (Case 2)

 Splice out adjacent successor block, coalesce both memory blocks, and insert the new block at the root of the list

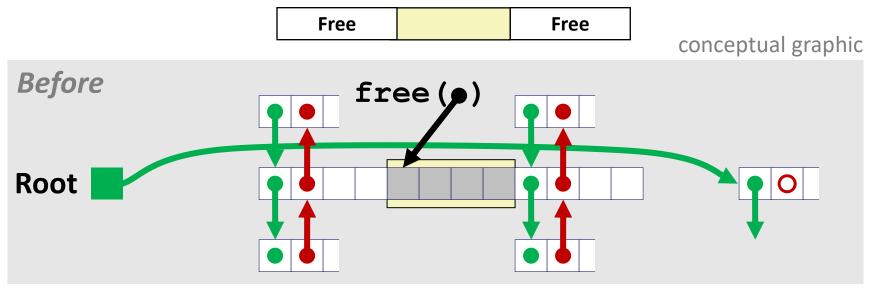

Freeing With a LIFO Policy (Case 3)

 Splice out adjacent predecessor block, coalesce both memory blocks, and insert the new block at the root of the list

Freeing With a LIFO Policy (Case 4)

 Splice out adjacent predecessor and successor blocks, coalesce all 3 blocks, and insert the new block at the root of the list

Explicit List Summary

Comparison to implicit list:

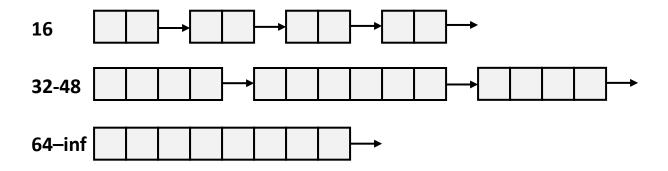

- Allocate is linear time in number of free blocks instead of all blocks
 - Much faster when most of the memory is full
- Slightly more complicated allocate and free
 - Need to splice blocks in and out of the list
- Some extra space for the links (2 extra words needed for each block)
 - Does this increase internal fragmentation?

Today

- **■** Explicit free lists
- Segregated free lists
- Memory-related perils and pitfalls

Segregated List (Seglist) Allocators

Have several free lists, one for each size class of blocks

- Which blocks go in which size classes is a design decision
 - Can have major impact on both utilization and throughput
 - Common choices include:
 - One class for each small size (16, 32, 48, 64, ...)
 - At some point switch to powers of two: $[2^i + 1, 2^{i+1}]$
- The list for the largest blocks must have no upper limit
 - (well, 2⁶⁴)

Seglist Allocator

Given an array of free lists, each one for some size class

■ To allocate a block of size n:

- Search appropriate free list for block of size $m \ge n$ (i.e., first fit)
- If an appropriate block is found:
 - Split block and place fragment on appropriate list
 - If no block is found, try next larger class
- Repeat until block is found

If no block is found:

- Request additional heap memory from OS (using sbrk ())
- Allocate block of n bytes from this new memory
- Place remainder as a single free block in appropriate size class.

Seglist Allocator (cont.)

- To free a block:
 - Coalesce and place on appropriate list
- Advantages of seglist allocators vs. non-seglist allocators (both with first-fit)
 - Higher throughput
 - log time for power-of-two size classes vs. linear time
 - Better memory utilization
 - First-fit search of segregated free list approximates a best-fit search of entire heap.
 - Extreme case: Giving each block its own size class is equivalent to best-fit.

Today

- **Explicit free lists**
- Segregated free lists
- Memory-related perils and pitfalls

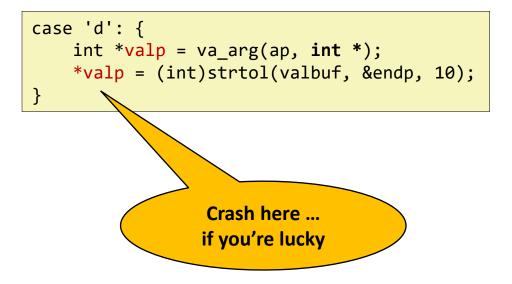

Memory-Related Perils and Pitfalls

- Dereferencing bad pointers
- Reading uninitialized memory
- Overwriting memory
- Referencing nonexistent variables
- Freeing blocks multiple times
- Referencing freed blocks
- Failing to free blocks

Dereferencing Bad Pointers

■ The classic scanf bug

```
int val;
...
scanf("%d", val);
```

Reading Uninitialized Memory

Assuming that heap data is initialized to zero

```
/* return y = Ax */
int *matvec(int **A, int *x) {
   int *y = malloc(N*sizeof(int));
   int i, j;
   for (i=0; i<N; i++)
      for (j=0; j<N; j++)
         y[i] += A[i][j]*x[j];
   return y;
```

Can avoid by using calloc

Allocating the (possibly) wrong sized object

```
int **p;

p = malloc(N*sizeof(int));

for (i=0; i<N; i++) {
   p[i] = malloc(M*sizeof(int));
}</pre>
```

Can you spot the bug?

Off-by-one errors

```
char **p;

p = malloc(N*sizeof(int *));

for (i=0; i<=N; i++) {
   p[i] = malloc(M*sizeof(int));
}</pre>
```

```
char *p;
p = malloc(strlen(s));
strcpy(p,s);
```

Not checking the max string size

```
char s[8];
int i;
gets(s); /* reads "123456789" from stdin */
```

Basis for classic buffer overflow attacks

Misunderstanding pointer arithmetic

```
int *search(int *p, int val) {
  while (p && *p != val)
    p += sizeof(int);

return p;
}
```

Referencing a pointer instead of the object it points to

```
int *BinheapDelete(int **binheap, int *size) {
   int *packet;
   packet = binheap[0];
   binheap[0] = binheap[*size - 1];
   *size--;
   Heapify(binheap, *size, 0);
   return(packet);
}
```

- What gets decremented?
 - (See next slide)

left to right left to right

left to right

right to left right to left

left to right

Overwriting Memory

Referencing a pointer instead of the object it points to

```
int *BinheapDelete(int **binheap, int *size) {
  int *packet;
  packet = binheap[0];
  binheap[0] = binheap[*size - 1];
  *size--;
  Heapify(binheap, *size, 0);
  return(packet);
}

Operators
() [] -> . ++---
left to right
```

Same effect as

```
size--;
```

Rewrite as

```
■ (*size)--;
```

Referencing Nonexistent Variables

Forgetting that local variables disappear when a function returns

```
int *foo () {
   int val;

return &val;
}
```

Freeing Blocks Multiple Times

Nasty!

Referencing Freed Blocks

Evil!

Failing to Free Blocks (Memory Leaks)

Slow, long-term killer!

```
foo() {
   int *x = malloc(N*sizeof(int));
   ...
   return;
}
```

Failing to Free Blocks (Memory Leaks)

Freeing only part of a data structure

```
struct list {
   int val;
   struct list *next;
};
foo() {
   struct list *head = malloc(sizeof(struct list));
   head->val = 0;
   head->next = NULL;
   <create and manipulate the rest of the list>
   free (head) ;
   return;
```

Dealing With Memory Bugs

- Debugger: gdb
 - Good for finding bad pointer dereferences
 - Hard to detect the other memory bugs
- Data structure consistency checker
 - Runs silently, prints message only on error
 - Use as a probe to zero in on error
- Binary translator: valgrind
 - Powerful debugging and analysis technique
 - Rewrites text section of executable object file
 - Checks each individual reference at runtime
 - Bad pointers, overwrites, refs outside of allocated block
- glibc malloc contains checking code
 - setenv MALLOC_CHECK_ 3
