# **System-level Programming I:**

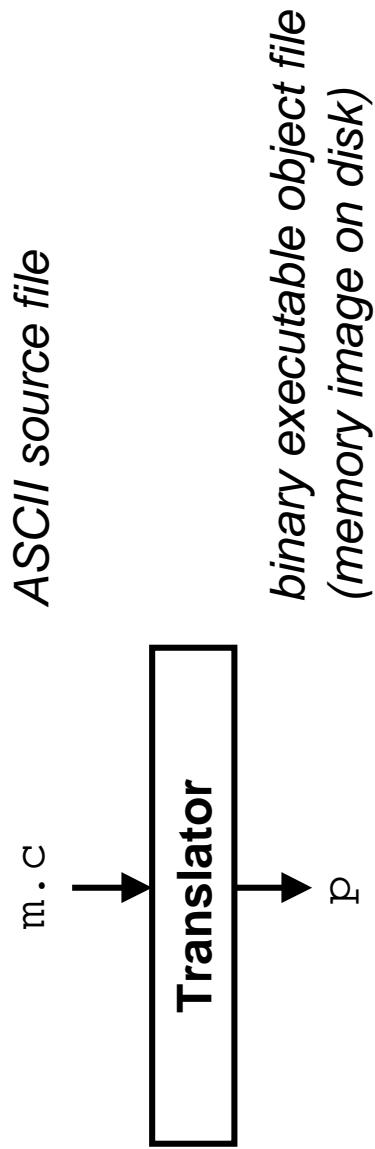

## **Building and running programs**

### **Feb. 22, 2000**

#### **Topics**

- static linking
- object files
- static libraries
- loading
- dynamic linking of shared libraries

# A simplistic program translation scheme

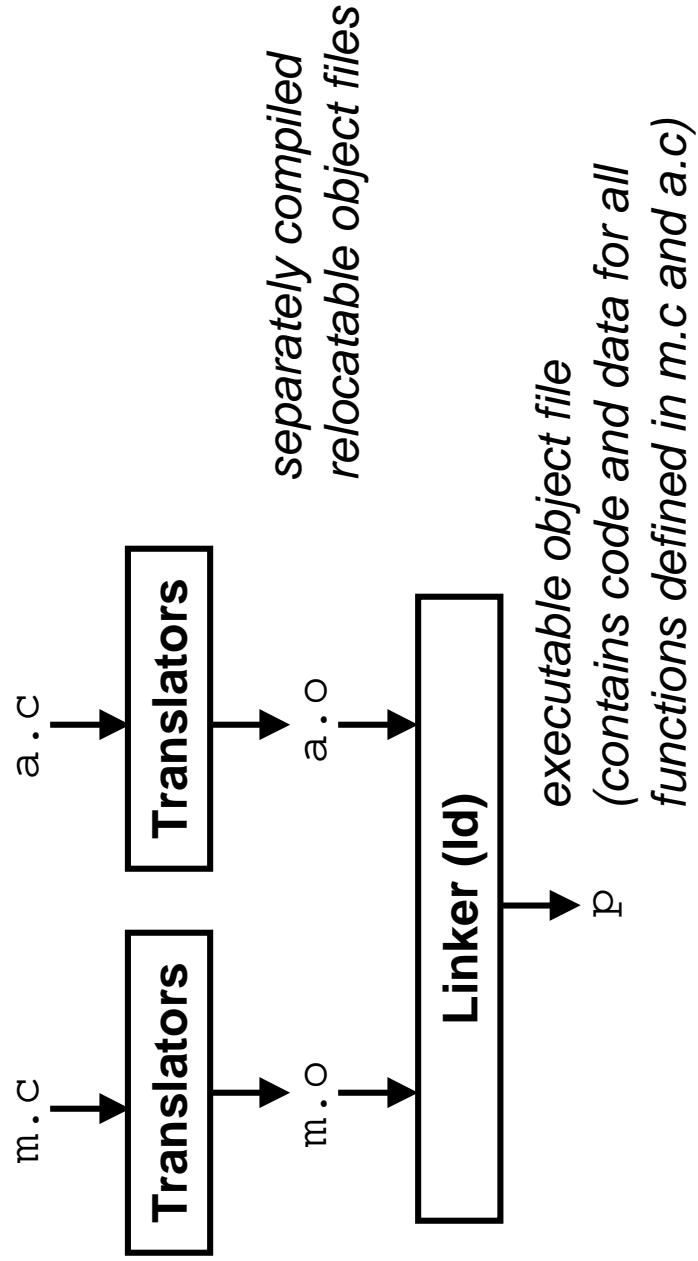

## Problems:

- efficiency: small change requires complete recompilation
- modularity: hard to share common functions (e.g. print)

## Solution:

- *static linker* (or *linker*)

# Linkers

# Translating the example program

*Compiler driver coordinates all steps in the translation and linking process.*

- Typically included with each compilation system (e.g., gcc)
- Invokes preprocessor (cpp), compiler (cc1), assembler (as), and linker (ld).

- Passes command line args to appropriate phases

**Example: create executable p from m.c and a.c:**

```
bass> gcc -O2 -v -o p m.c a.c
cpp [args] m.c /tmp/ccaa07630.i
cc1 /tmp/ccaa07630.i m.c -O2 [args] -o /tmp/ccaa07630.s
as [args] -o /tmp/ccaa076301.o /tmp/ccaa07630.s
<similar process for a.c>
ld -o p [system obj files] /tmp/ccaa076301.o /tmp/ccaa076302.o
bass>
```

# What does a linker do?

## Merges object files

- merges multiple *relocatable* (.o) object files into a single *executable* object file that can be loaded and executed by the loader.

## Resolves external references

- as part of the merging process, resolves *external references*.
  - *external reference*: reference to a symbol defined in another object file.

## Relocates symbols

- relocates *symbols* from their relative locations in the .o files to new absolute positions in the executable.
- updates all references to these symbols to reflect their new positions.
  - references can be in either code or data

```
» code: a( ) ; /* ref to symbol a */  
» data: int *xp=&x; /* ref to symbol x */
```

- because of this modifying, linking is sometimes called *link editing*.

# Why linkers?

## Modularity

- Program can be written as a collection of smaller source files, rather than one monolithic mass.
- Can build libraries of common functions (more on this later)
  - e.g., math library, standard C library
- Efficiency
  - Time:
    - change one source file, compile, and then relink.
    - no need to recompile other source files.
  - Space:
    - libraries of common functions can be aggregated into a single file...
    - yet executable files and running memory images contain only code for the functions they actually use.

# **Executable and linkable format (ELF)**

**Standard binary format for object files**

**Derives from AT&T System V Unix**

- later adopted by BSD Unix variants and Linux

**One unified format for relocatable object files (.o), executable object files, and shared object files (.so)**

- generic name: ELF binaries

**Better support for shared libraries than old a.out formats.**

# ELF object file format

## Elf header

- magic number, type (.o, exec, .so), machine, byte ordering, etc.

## Program header table

- page size, virtual addresses for memory segments (sections), segment sizes.

## .text section

- code

## .data section

- initialized (static) data

## .bss section

- uninitialized (static) data
- “Block Started by Symbol”
- “Better Save Space”
- has section header but occupies no space

0

## ELF header

Program header table  
(required for executables)

## .text section

## .data section

## .bss section

## .symtab

## .rel.txt

## .rel.data

## .debug

Section header table  
(required for relocatables)

# ELF object file format

## .symtab

- symbol table
- procedure and static variable names
- section names and locations

## .rel.text

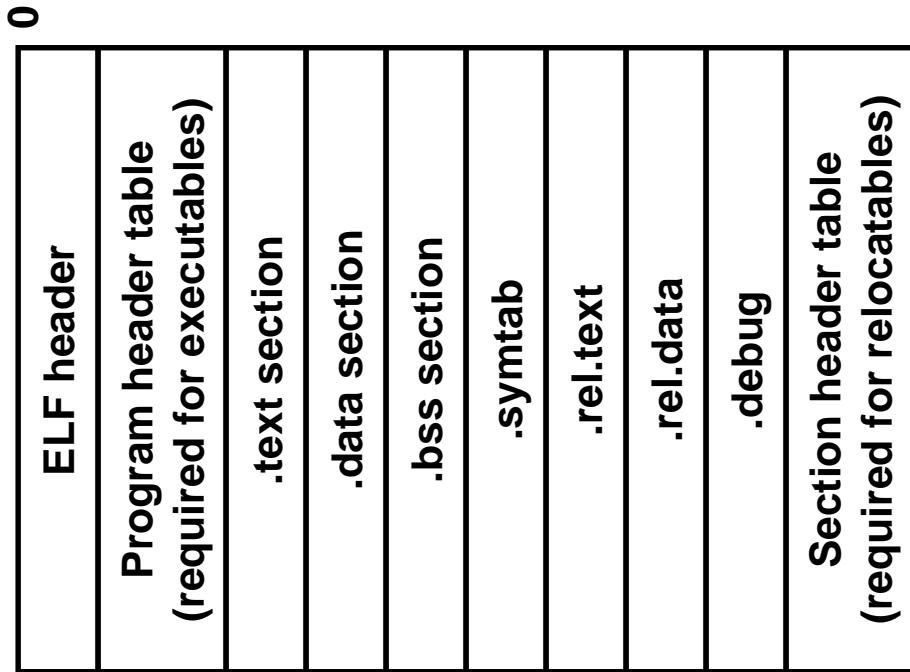

- relocation info for .text section
- addresses of instructions that will need to be modified in the executable
- instructions for modifying.

## .rel.data

- relocation info for .data section
- addresses of pointer data that will need to be modified in the merged executable

## .debug

- info for symbolic debugging (gcc -g)

# Example C program

m.c

```
int e=7;

int main() {
    int r = a();
    exit(0);
}
```

a.c

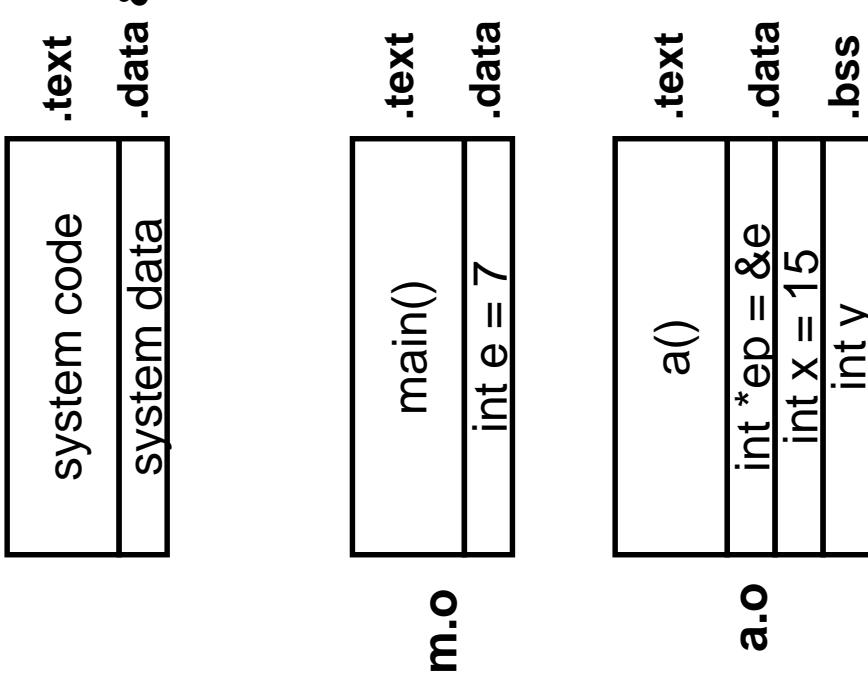

```
extern int e;

int *ep=&e;
int x=15;
int y;

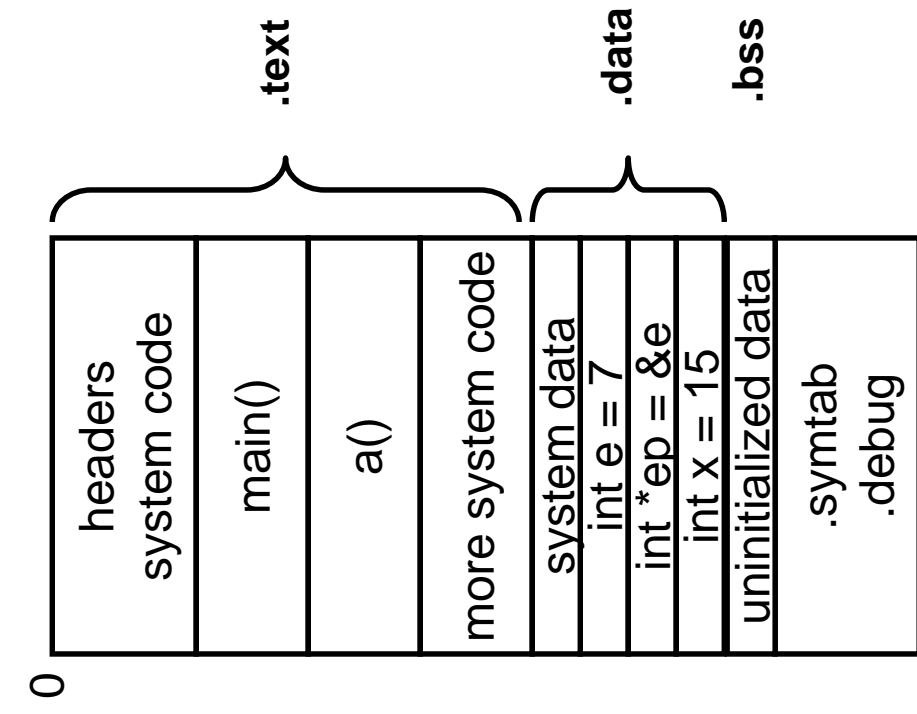

int a() {
    return *ep+x+y;
}
```

# Merging .o files into an executable

Relocatable object files

Executable object file

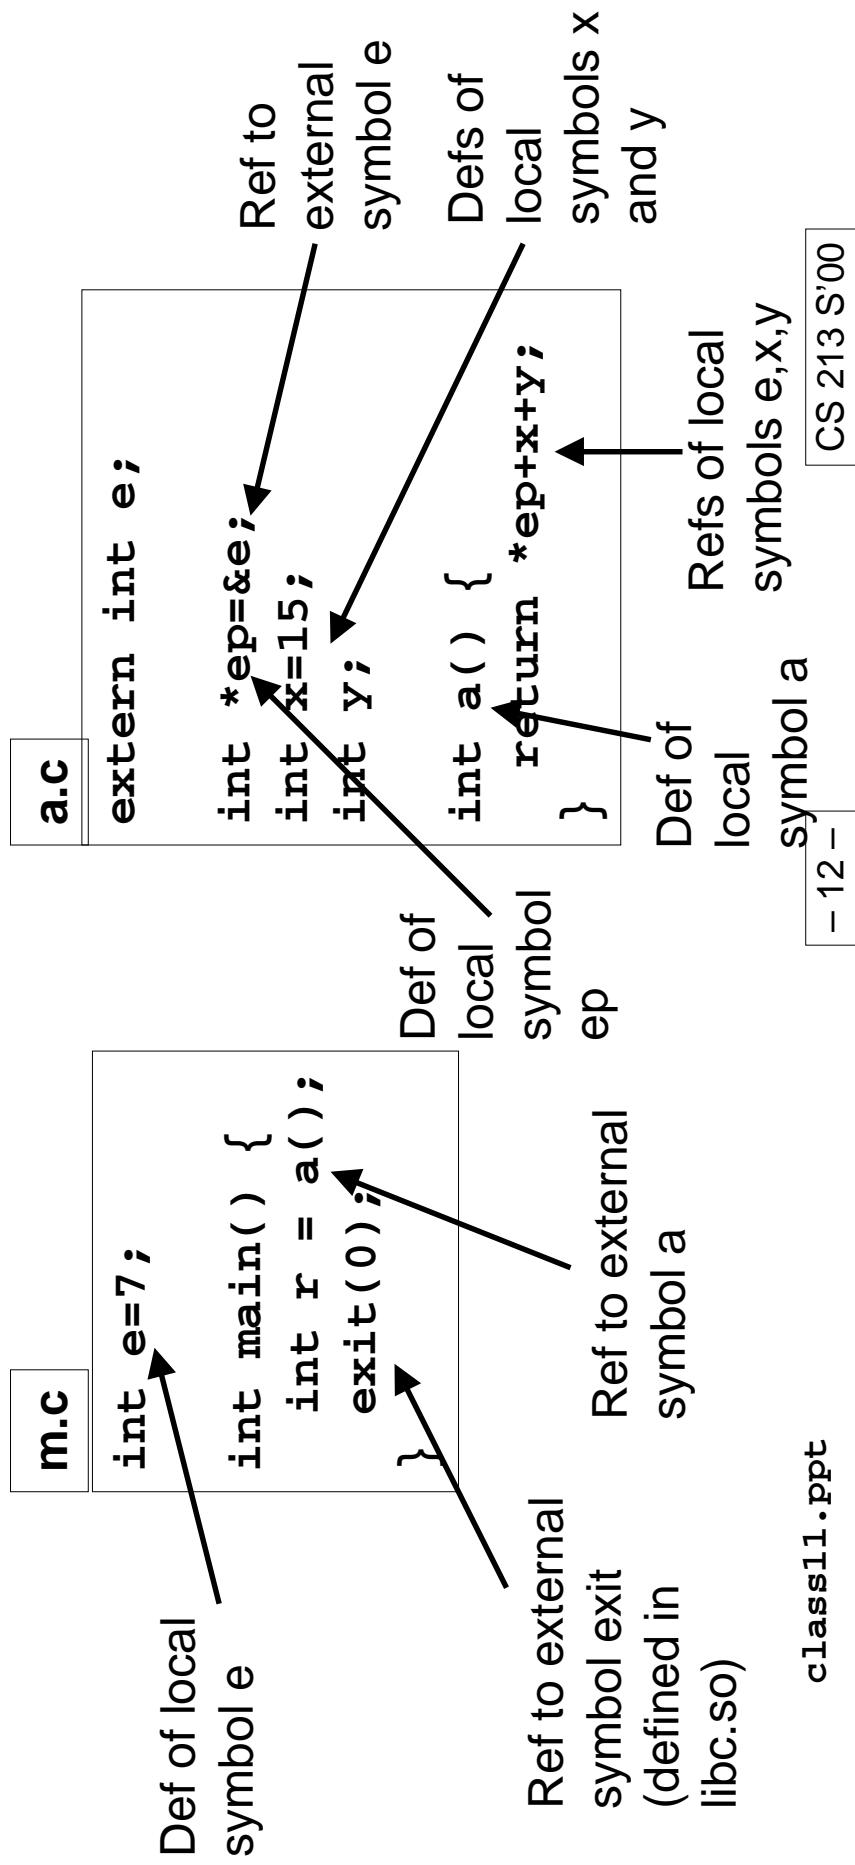

# Relocating symbols and resolving external references

Symbols are lexical entities that name functions and variables.

Each symbol has a *value* (typically a memory address).

Code consists of symbol **definitions** and **references**.

References can be either *local* or *external*.

# m.o relocation info

m.c

```
int e=7;
```

```
int main() {  
    int r = a();  
    exit(0);  
}
```

Disassembly of section .text:

```
00000000 <main>: 00000000 <main>  
0: 55          pushl %ebp  
1: 89 e5       movl %esp, %ebp  
3: e8 fc ff ff call 4 <main+0x4>  
4: R_386_PC32 a  
  
8: 6a 00       pushl $0x0  
a: e8 fc ff ff call b <main+0xb>  
b: R_386_PC32 exit  
f: 90          nop
```

Disassembly of section .data:

```
00000000 <e>:  
0: 07 00 00 00
```

# Strong and weak symbols

Program symbols are either **strong** or **weak**

- strong: procedures and initialized globals
- weak: uninitialized globals

# Linker's symbol rules

1. A **strong symbol** can only appear once.
2. A **weak symbol** can be overridden by a **strong symbol of the same name**.
  - references to the **weak symbol resolve to the strong symbol**.
3. If **multiple weak symbols**, the linker can pick either one.

# Symbol resolution examples

```
int x;  
p1() {}
```

link time error: two strong symbols (p1)

```
int x;  
p1() {}  
int x;  
p2() {}
```

both instances of x refer to the same  
uninitialized int.

```
int x;  
int y;  
p1() {}  
double x;  
p2() {}
```

writes to x in p2 might overwrite y!  
Evil!

```
int x=7;  
int y=5;  
p1() {}  
double x;  
p2() {}
```

writes to x in p2 will overwrite something!  
Nasty!

```
int x=7;  
p1() {}  
int x;  
p2() {}
```

references to x refer to the same initialized  
variable.

**Nightmare scenario:** two identical weak structs, compiled by different compilers  
with different alignment rules.

# Packaging commonly used functions

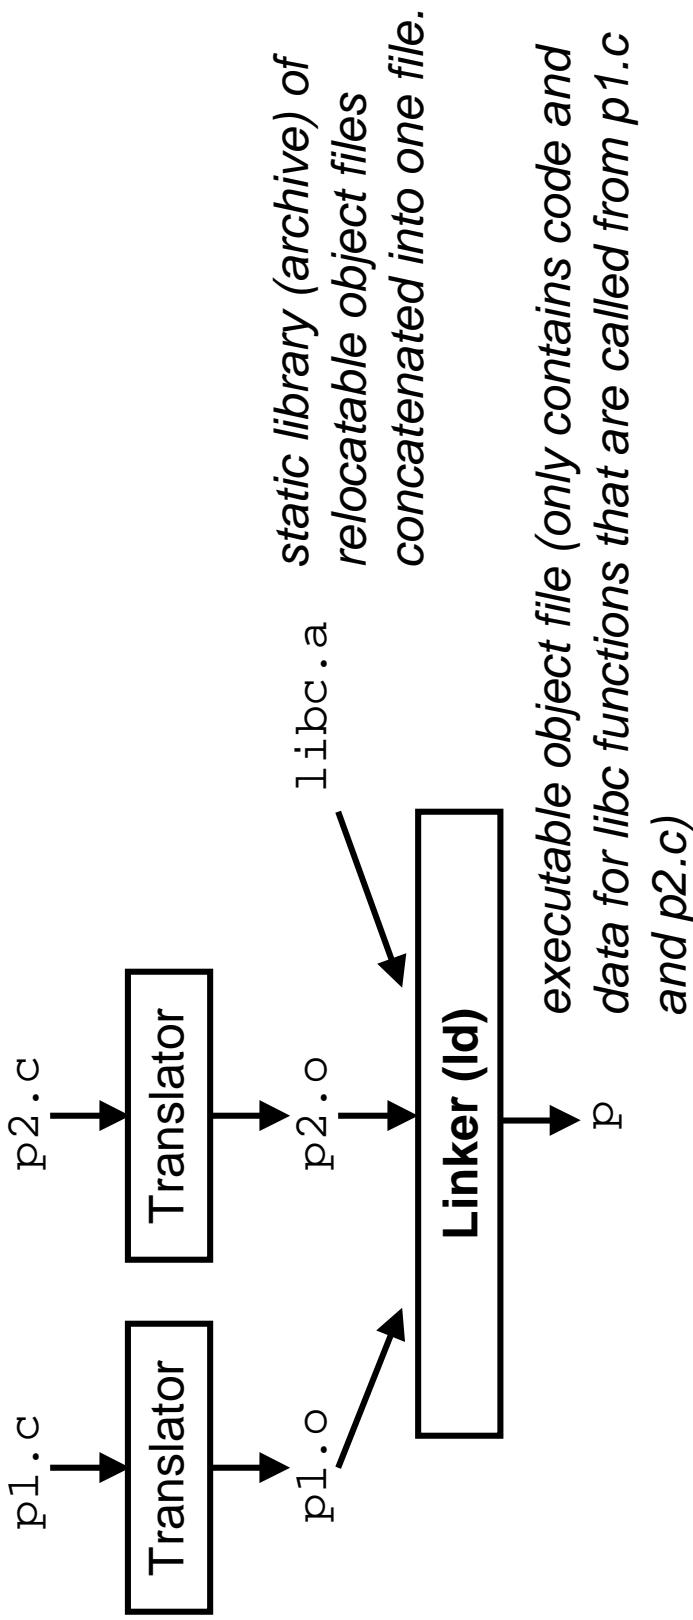

How to package functions commonly used by programmers?

- math, I/O, memory management, string manipulation, etc.

Awkward, given the linker framework so far:

- Option 1: Put all functions in a single source file
    - programmers link big object file into their programs
    - space and time inefficient
  - Option 2: Put each function in a separate source file
    - programmers explicitly link appropriate binaries into their programs
    - more efficient, but burdensome on the programmer
- Solution: static libraries (.a archive files)**
- concatenate related relocatable object files into a single file with an index (called an archive).
  - enhance linker so that it tries to resolve unresolved external references by looking for the symbols in one or more archives.
  - If an archive member file resolves reference, link into executable.

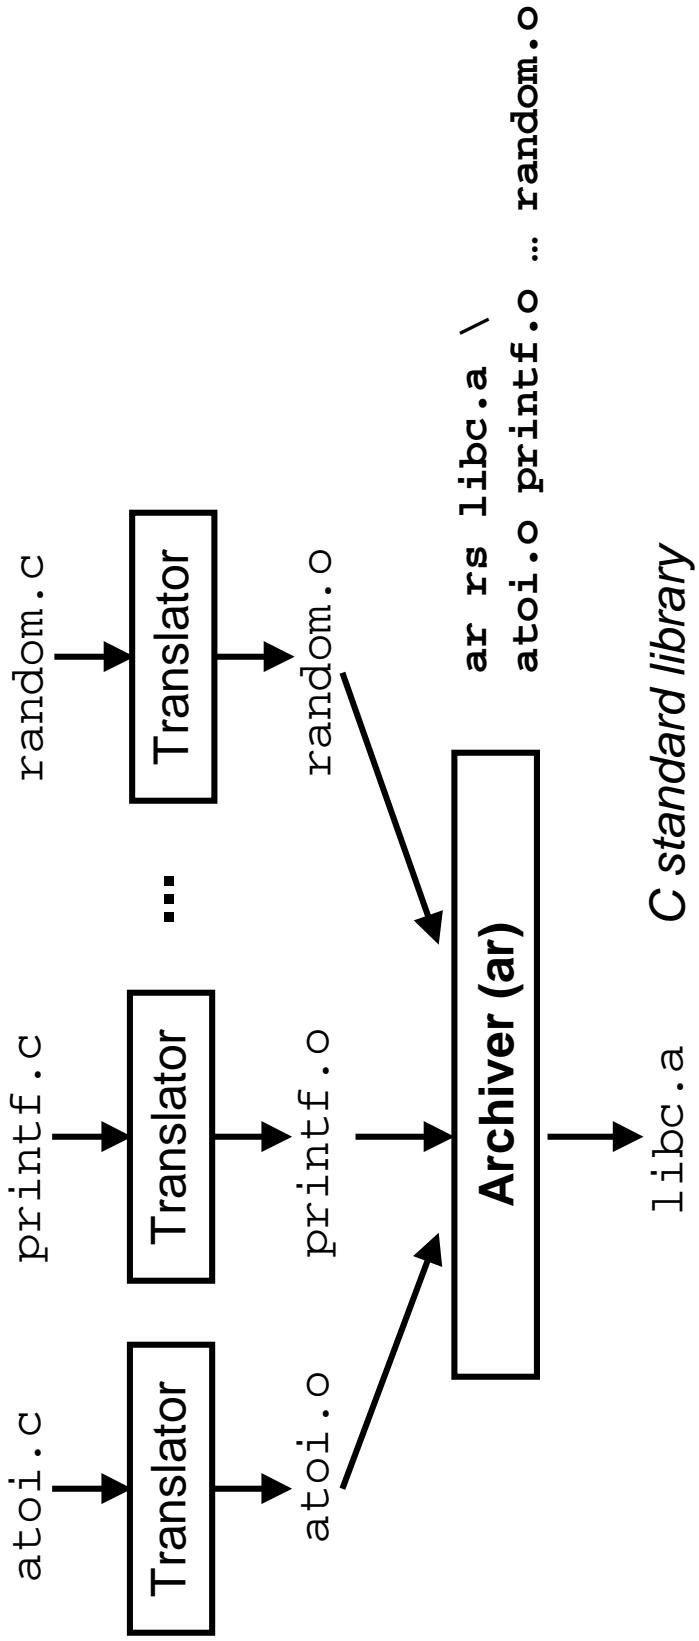

# Static libraries (archives)

Further improves modularity and efficiency by packaging commonly used functions (e.g., C standard library, math library)

Linker selectively only the .o files in the archive that are actually needed by the program.

# Creating static libraries

Archiver allows incremental updates:

- recompile function that changes and replace .o file in archive.

# Commonly used libraries

## libc.a (the C standard library)

- 8 MB archive of 900 object files.
- I/O, memory allocation, signal handling, string handling, data and time, random numbers, integer math

## libm.a (the C math library)

- 1 MB archive of 226 object files.
- floating point math (sin, cos, tan, log, exp, sqrt, ...)

```
% ar -t /usr/lib/libc.a | sort
...
fork.o
...
fprintf.o
fpu_control.o
fputc.o
freopen.o
fscanf.o
fseek.o
fstab.o
...
...
```

```
% ar -t /usr/lib/libm.a | sort
...
e_acos.o
e_acosf.o
e_acosh.o
e_acoshf.o
e_acoshl.o
e_acosl.o
e_asin.o
e_asinf.o
e_asinl.o
...
...
```

# Using static libraries

**Linker's algorithm for resolving external references:**

- Scan .o files and .a files in the command line order.
- During the scan, keep a list of the current unresolved references.
- As each new .o or .a file *obj* is encountered, try to resolve each unresolved reference in the list against the symbols in *obj*.
- If any entries in the unresolved list at end of scan, then error.

**Problem:**

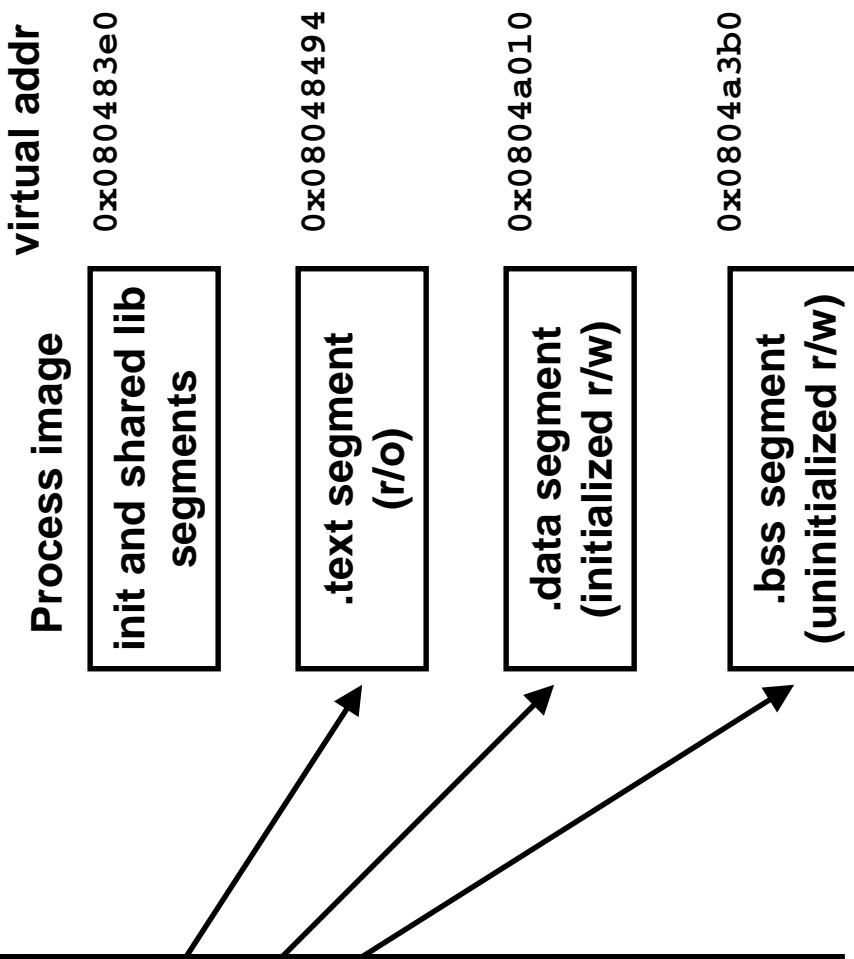

- command line order matters!
- Moral: put libraries at the end of the command line.

```
bass> gcc -L. libtest.o -lmine  
bass> gcc -L. -lmine libtest.o  
libtest.o: In function `main':  
libtest.o(.text+0x4): undefined reference to `libfun'
```

# Loading executable binaries

	.debug
	Section header table (required for relocatables)

# Shared libraries

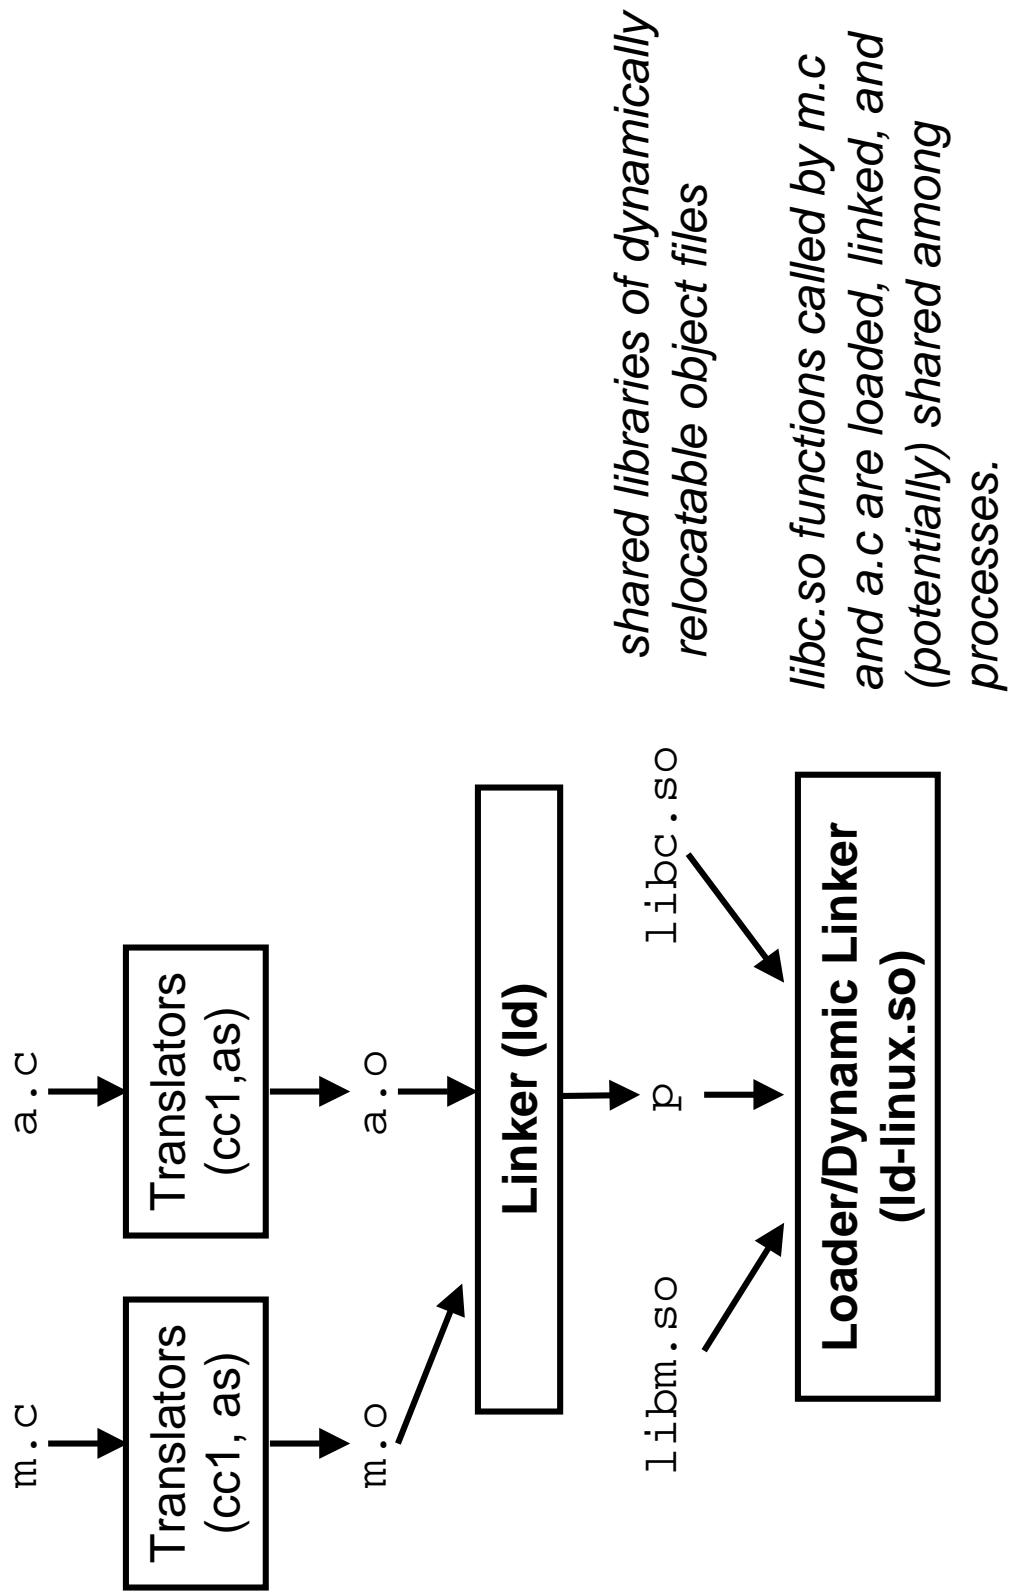

**Static libraries have the following disadvantages:**

- potential for duplicating lots of common code in the executable files on a filesystem.
  - e.g., every C program needs the standard C library
- potential for duplicating lots of code in the virtual memory space of many processes.
- minor bug fixes of system libraries require each application to explicitly relink

**Solution:**

- *shared libraries* (dynamic link libraries, DLLs) whose members are dynamically loaded into memory and linked into an application at run-time.
  - dynamic linking can occur when executable is first loaded and run.
    - » common case for Linux, handled automatically by ld-linux.so.
  - dynamic linking can also occur after program has begun.
    - » in Linux, this is done explicitly by user with dlopen().
  - shared library routines can be shared by multiple processes.

# Dynamically linked shared libraries

# The complete picture
