Lecture 2: **A Modern Multi-Core** Processor

(Forms of parallelism + understanding latency and bandwidth)

Parallel Computer Architecture and Programming CMU 15-418/15-618, Fall 2023

Today

Today we will talk computer architecture

Four key concepts about how modern computers work

- Two concern parallel execution
- Two concern challenges of accessing memory

Understanding these architecture basics will help you

- Understand and optimize the performance of your parallel programs
- Gain intuition about what workloads might benefit from fast parallel machines

Part 1: parallel execution

Example program

Compute sin(x) **using Taylor expansion:** $sin(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} \dots$ for each element of an array of N floating-point numbers

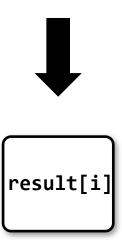

```
void sinx(int N, int terms, float* x, float* result)
{
   for (int i=0; i<N; i++)</pre>
   {
      float value = x[i];
      float numer = x[i] * x[i] * x[i];
      int denom = 6; // 3!
      int sign = -1;
      for (int j=1; j<=terms; j++)</pre>
      {
         value += sign * numer / denom;
         numer *= x[i] * x[i];
         denom *= (2*j+2) * (2*j+3);
         sign *= -1;
      }
      result[i] = value;
```

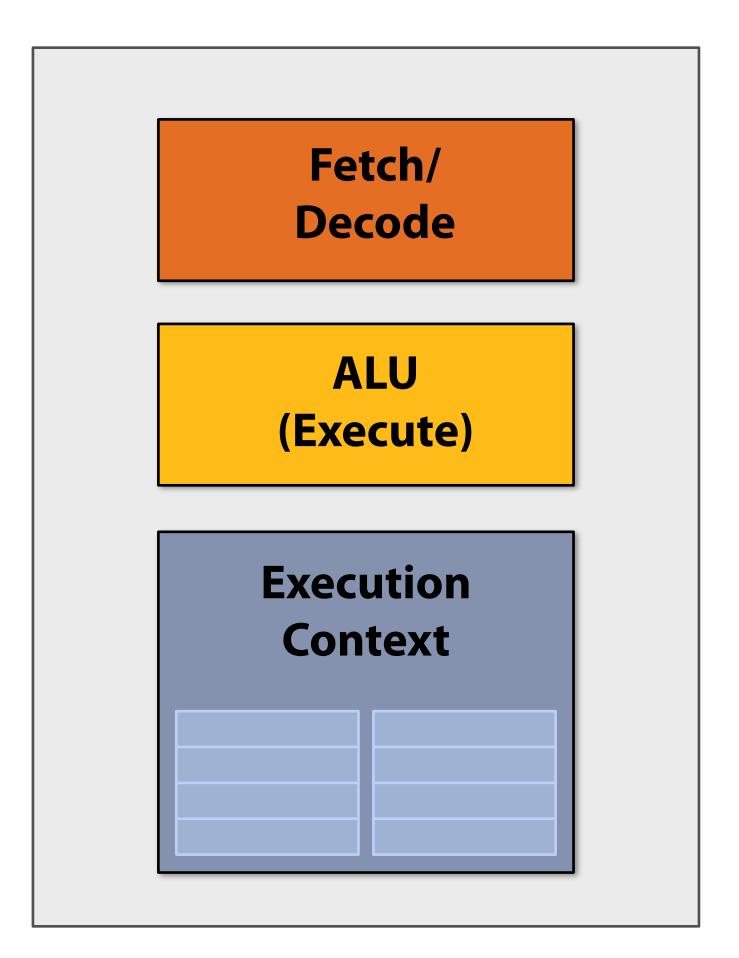

Compile program

```
void sinx(int N, int terms, float* x, float* result)
{
   for (int i=0; i<N; i++)</pre>
      float value = x[i];
      float numer = x[i] * x[i] * x[i];
      int denom = 6; // 3!
      int sign = -1;
      for (int j=1; j<=terms; j++)</pre>
      {
         value += sign * numer / denom;
         numer *= x[i] * x[i];
         denom *= (2*j+2) * (2*j+3);
         sign *= -1;
      }
      result[i] = value;
```

x[i]

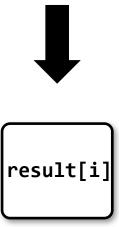

ld r0, addr[r1]
mul r1, r0, r0
mul r1, r1, r0
...
...
...
...
st addr[r2], r0

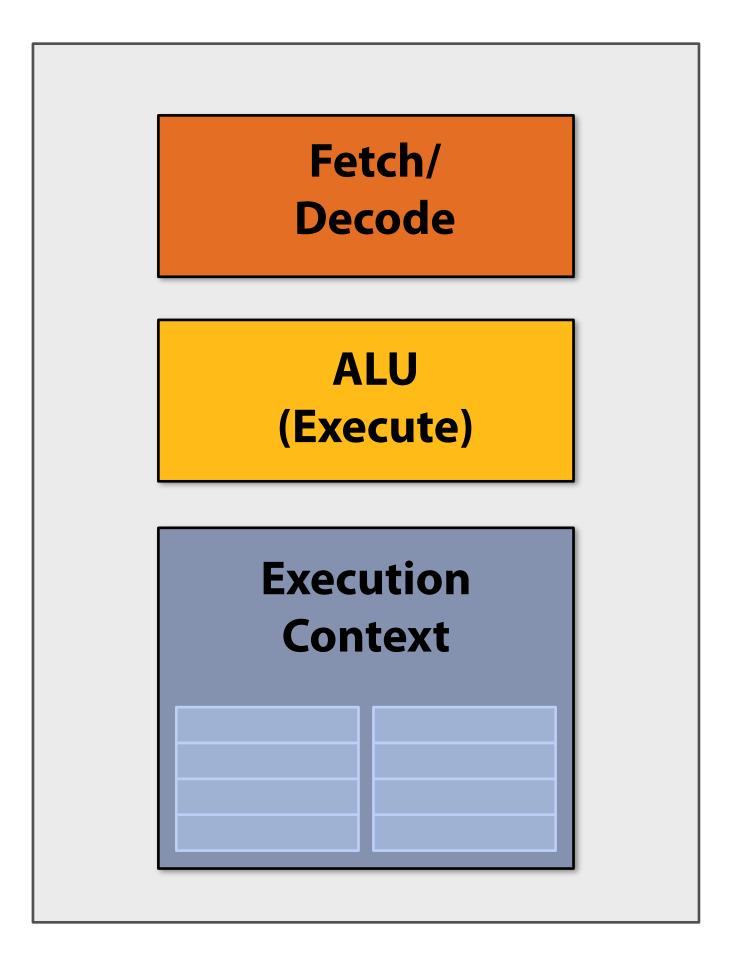

x[i]

1d r0, addr[r1]
mul r1, r0, r0
mul r1, r1, r0
...
...
...
...
st addr[r2], r0

My very simple processor: executes one instruction per clock

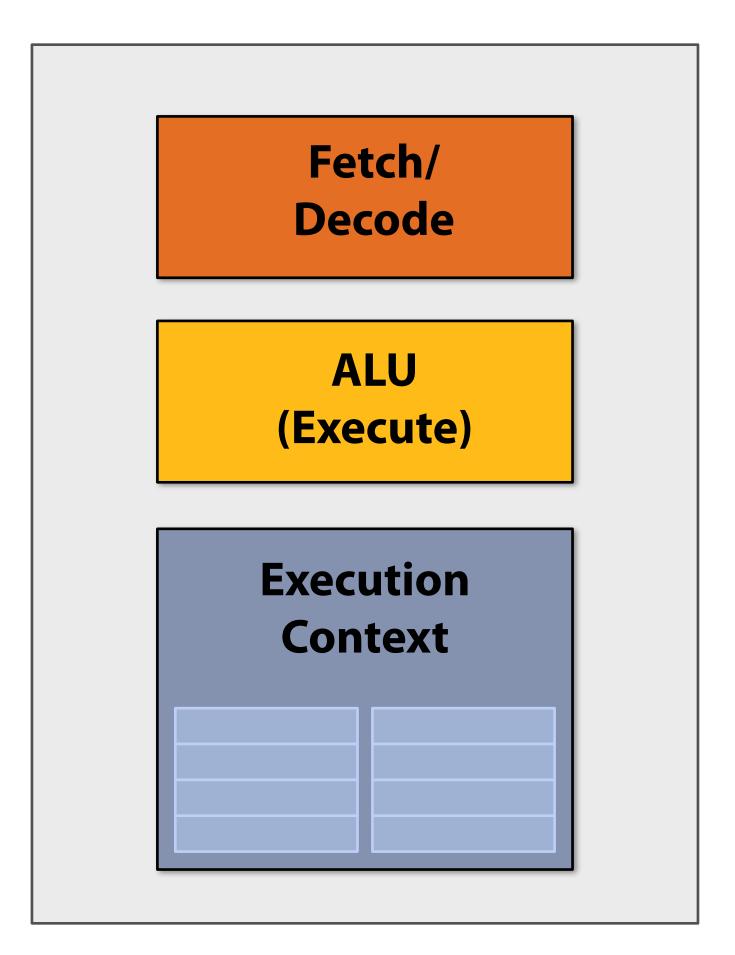

x[i]

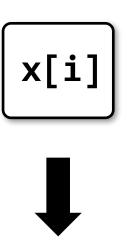

ld	r0, addr[r1]
mul	r1, r0, r0
mul	r1, r1, r0
• • •	
• • •	
• • •	
• • •	
• • •	
• • •	
st	addr[r2], r0

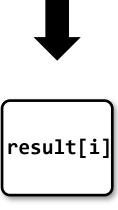

My very simple processor: executes one instruction per clock

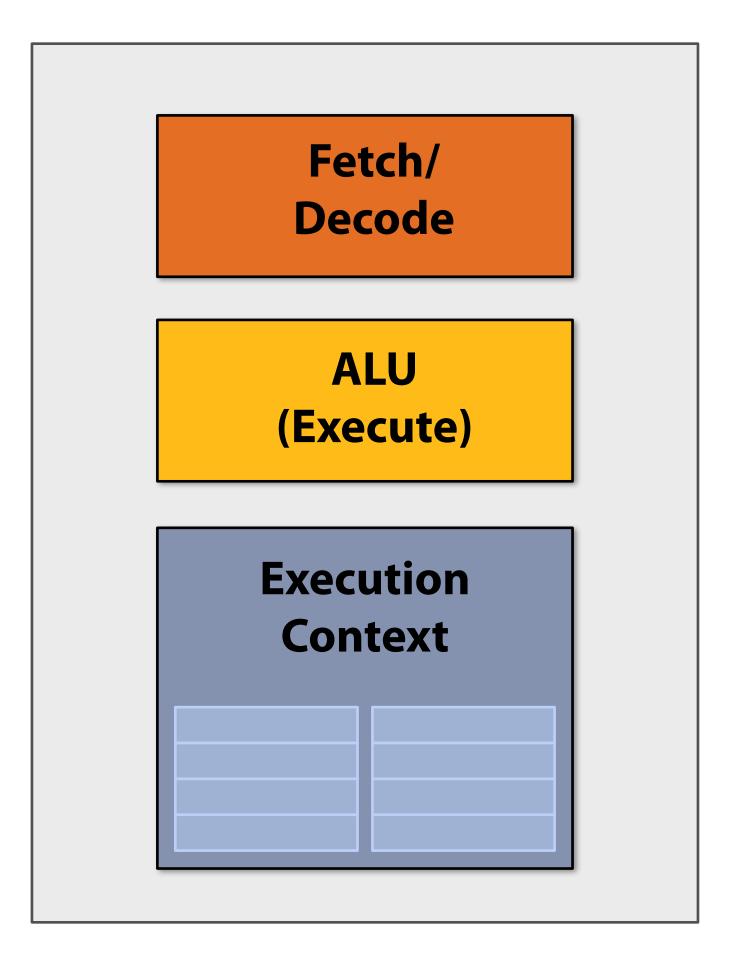

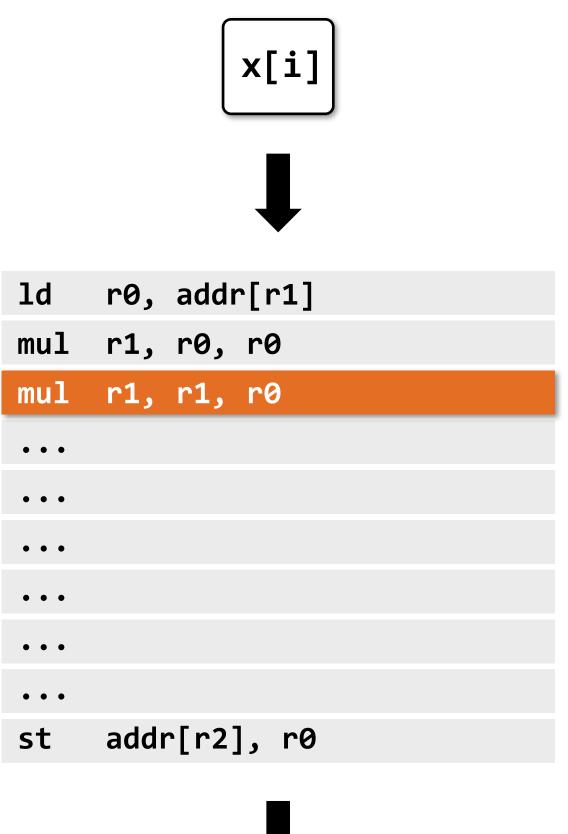

ld	r0, addr[r1]
	r1, r0, r0
mul	r1, r1, r0
• • •	
• • •	
• • •	
• • •	
• • •	
• • •	
st	addr[r2], r0

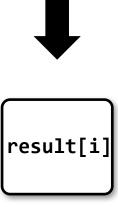

My very simple processor: executes one instruction per clock

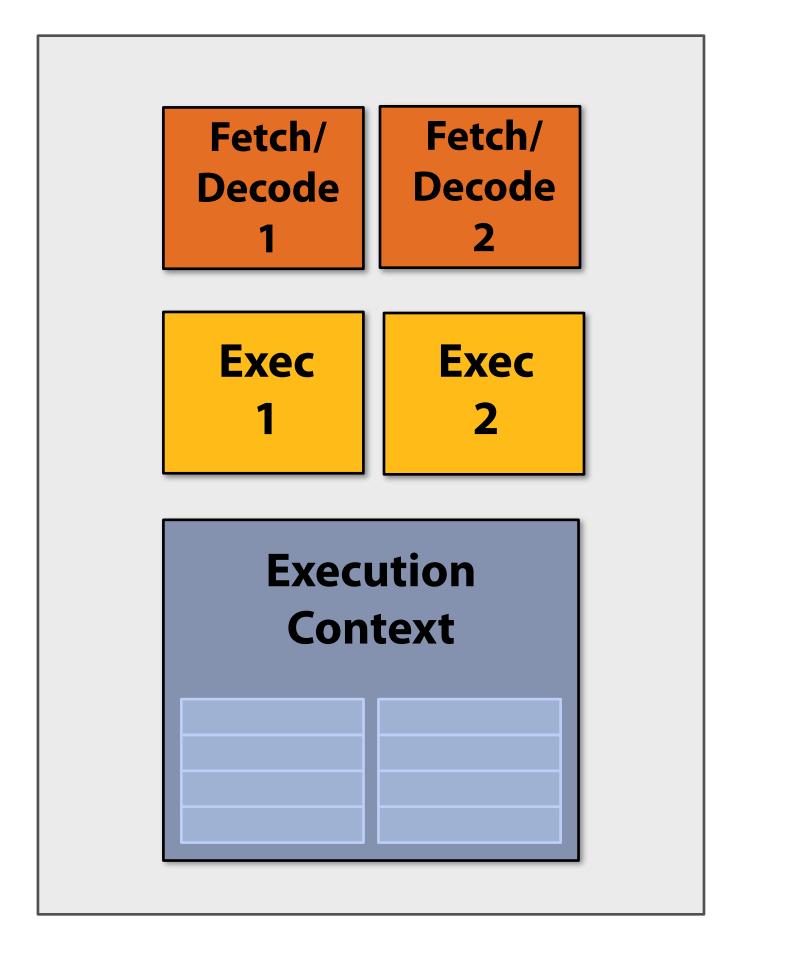

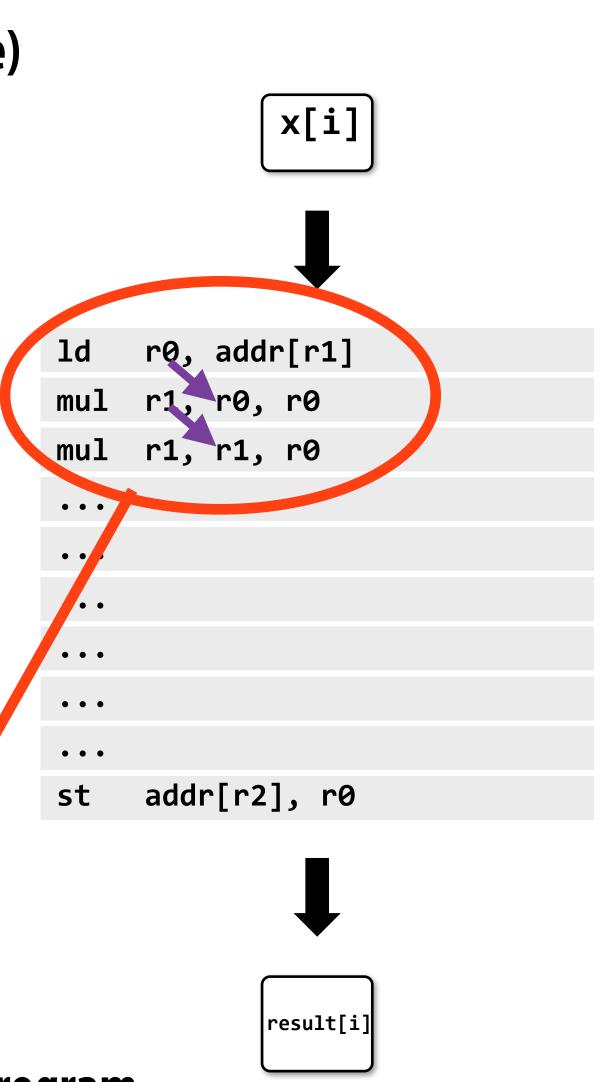

Superscalar processor

Recall from last class: instruction level parallelism (ILP) Decode and execute two instructions per clock (if possible)

Note: No ILP exists in this region of the program

Aside: Pentium 4

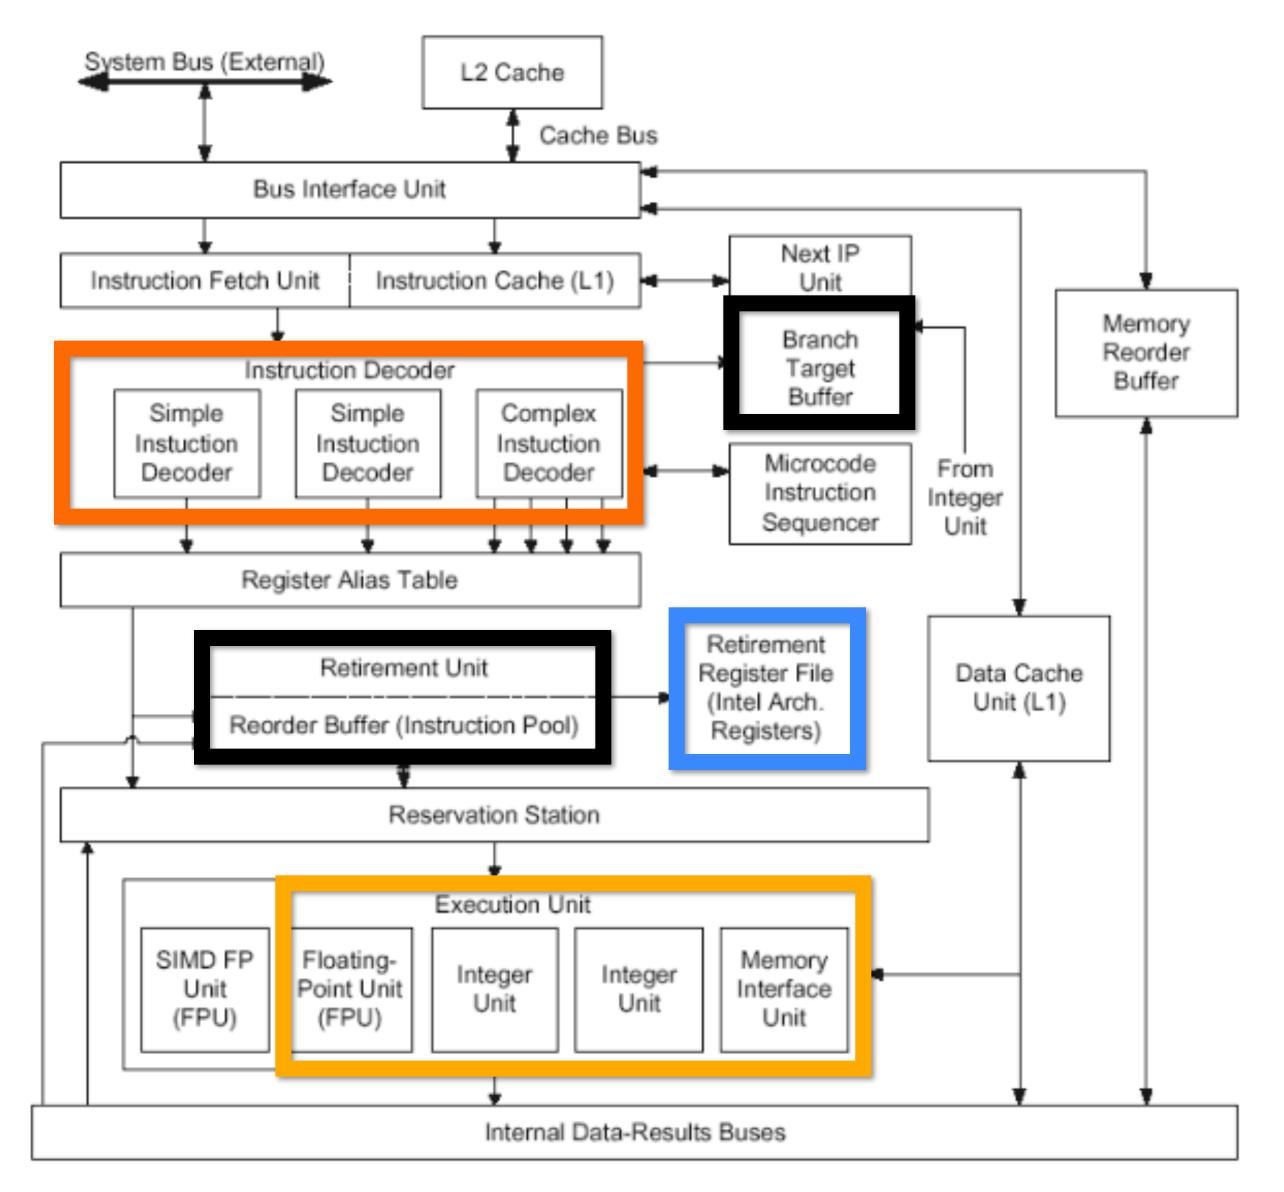

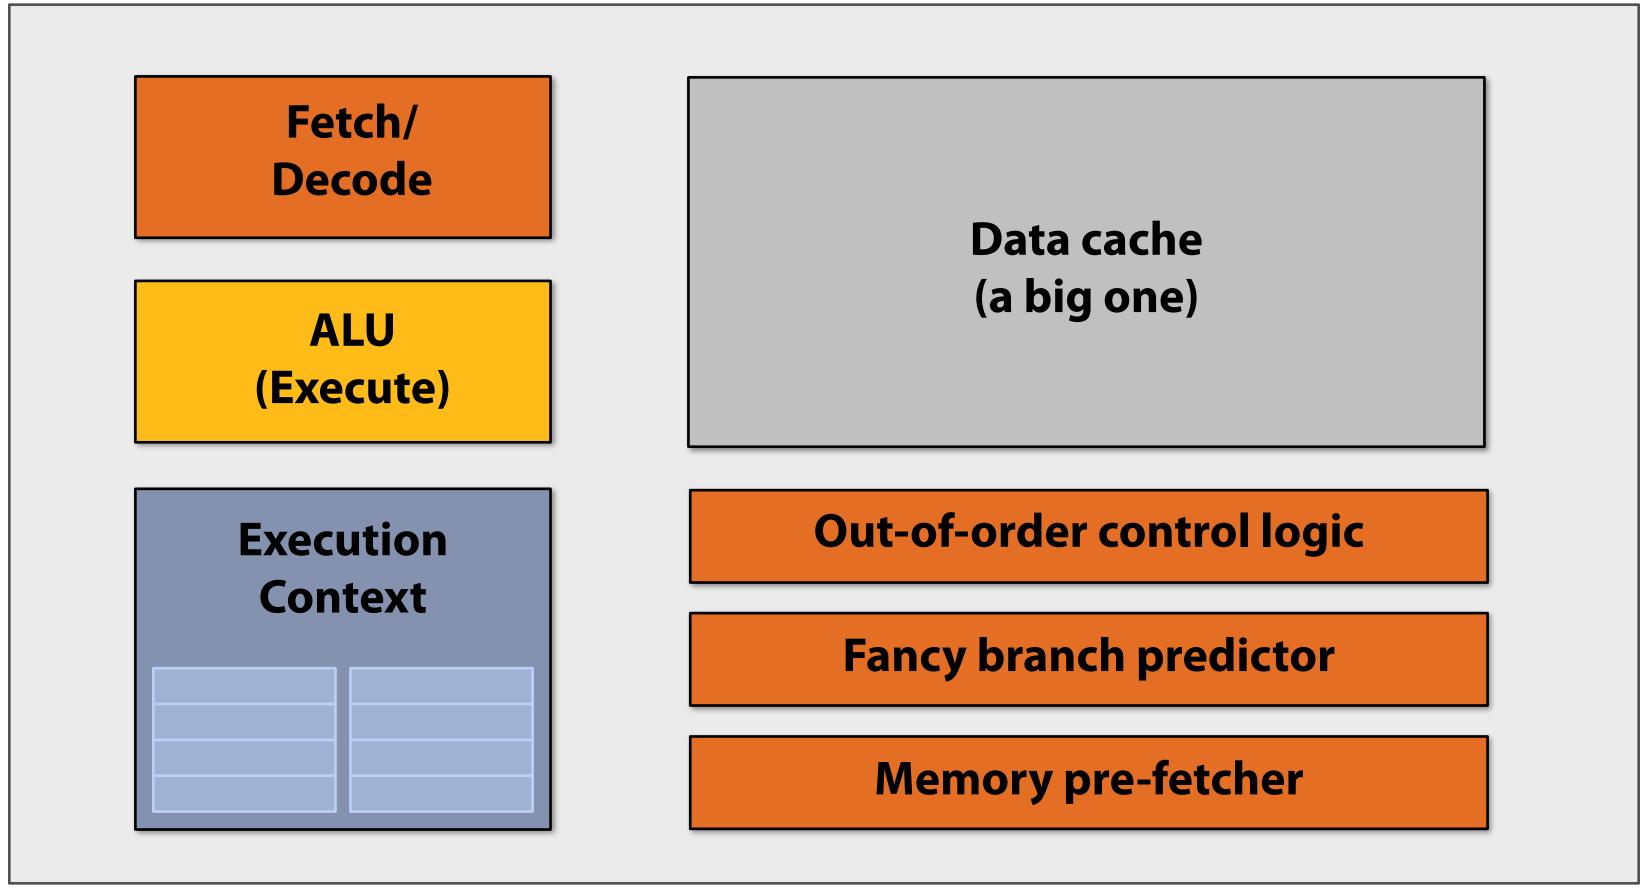

Image credit: http://ixbtlabs.com/articles/pentium4/index.html

Processor: pre multi-core era

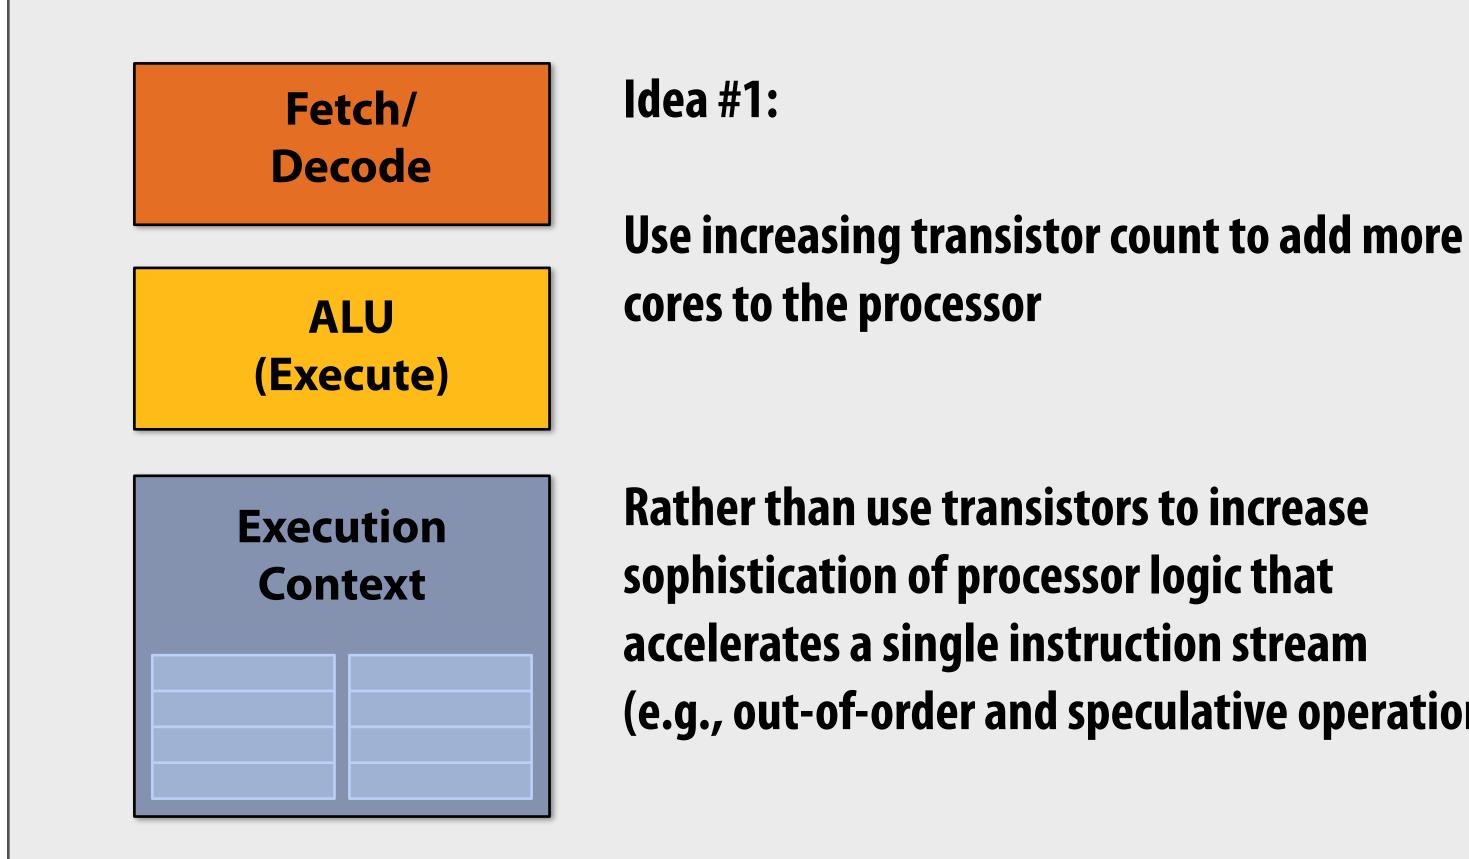

Majority of chip transistors used to perform operations

More transistors = larger cache, smarter out-of-order logic, smarter branch predictor, etc.

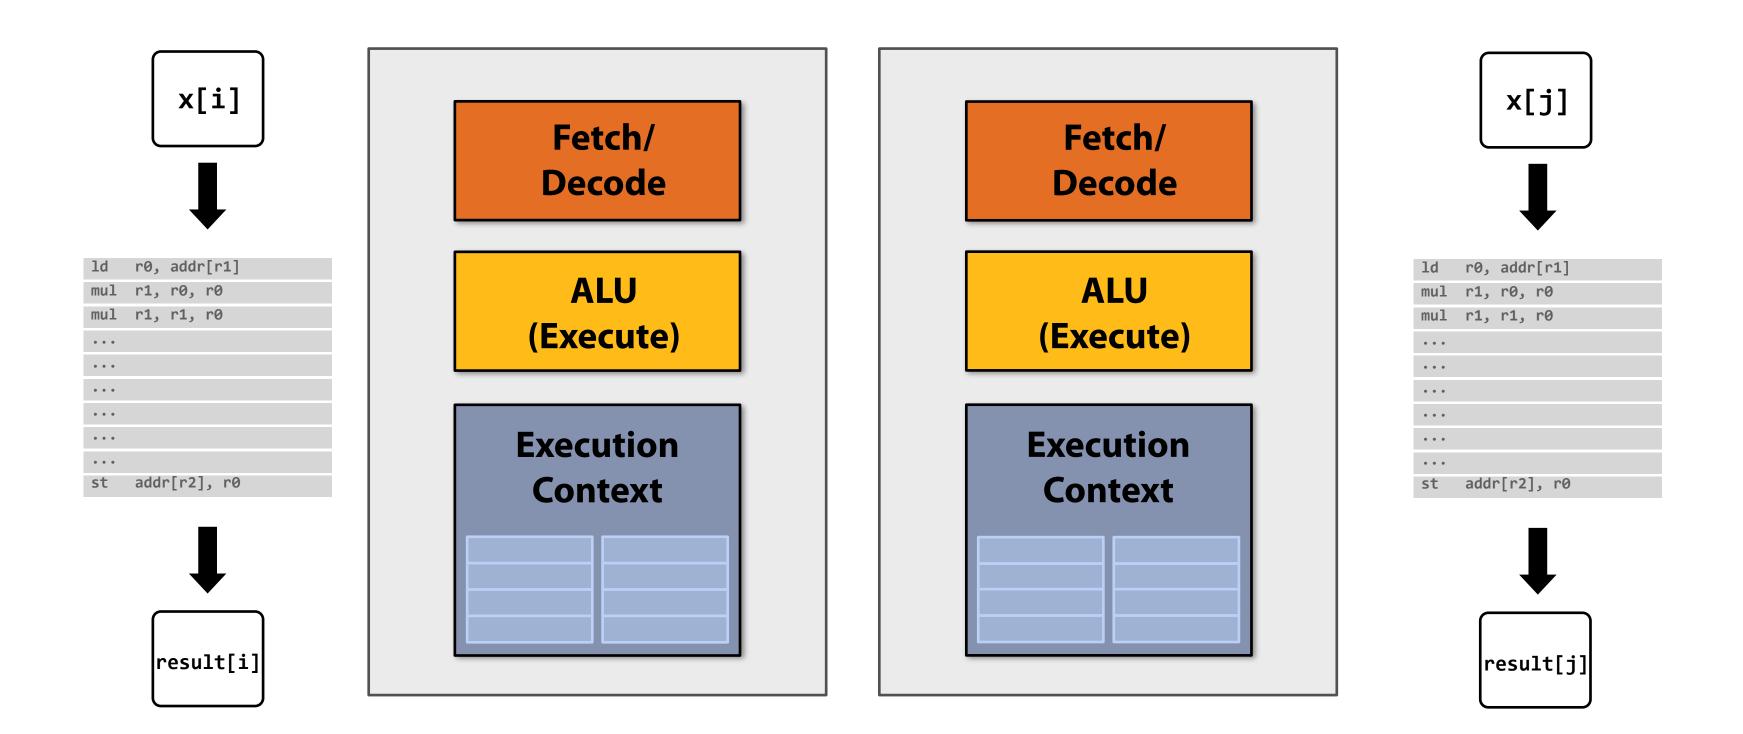

(Also: more transistors \rightarrow smaller transistors \rightarrow higher clock frequencies)

Processor: multi-core era

(e.g., out-of-order and speculative operations)

Two cores: compute two elements in parallel

Simpler cores: each core is slower at running a single instruction stream than our original "fancy" core (e.g., 0.75 times as fast)

But there are now two cores: $2 \times 0.75 = 1.5$

(potential for speedup!)

But our program expresses no parallelism

```
void sinx(int N, int terms, float* x, float* result)
{
   for (int i=0; i<N; i++)</pre>
   {
      float value = x[i];
      float numer = x[i] * x[i] * x[i];
      int denom = 6; // 3!
      int sign = -1;
      for (int j=1; j<=terms; j++)</pre>
      {
         value += sign * numer / denom;
         numer *= x[i] * x[i];
         denom *= (2*j+2) * (2*j+3);
         sign *= -1;
      }
      result[i] = value;
```

This program, compiled with gcc will run as one thread on one of the processor cores.

If each of the simpler processor cores was 0.75X as fast as the original single complicated one, our program now has a "speedup" of 0.75 (i.e. it is slower).

Expressing parallelism using pthreads

```
typedef struct {
  int N;
  int terms;
  float* x;
  float* result;
} my_args;
void parallel_sinx(int N, int terms, float* x, float* result)
{
    pthread_t thread_id;
   my_args args;
   args.N = N/2;
    args.terms = terms;
   args.x = x;
   args.result = result;
    pthread_create(&thread_id, NULL, my_thread_start, &args); // launch thread
    sinx(N - args.N, terms, x + args.N, result + args.N); // do work
    pthread_join(thread_id, NULL);
void my_thread_start(void* thread_arg)
{
   my_args* thread_args = (my_args*)thread_arg;
   sinx(args->N, args->terms, args->x, args->result); // do work
```

void sinx(int N, int terms, float* x, float* result)

```
for (int i=0; i<N; i++)</pre>
   float value = x[i];
   float numer = x[i] * x[i] * x[i];
   int denom = 6; // 3!
   int sign = -1;
   for (int j=1; j<=terms; j++)</pre>
    {
       value += sign * numer / denom
       numer *= x[i] * x[i];
       denom *= (2*j+2) * (2*j+3);
       sign *= -1;
   }
   result[i] = value;
```

{

}

Data-parallel expression

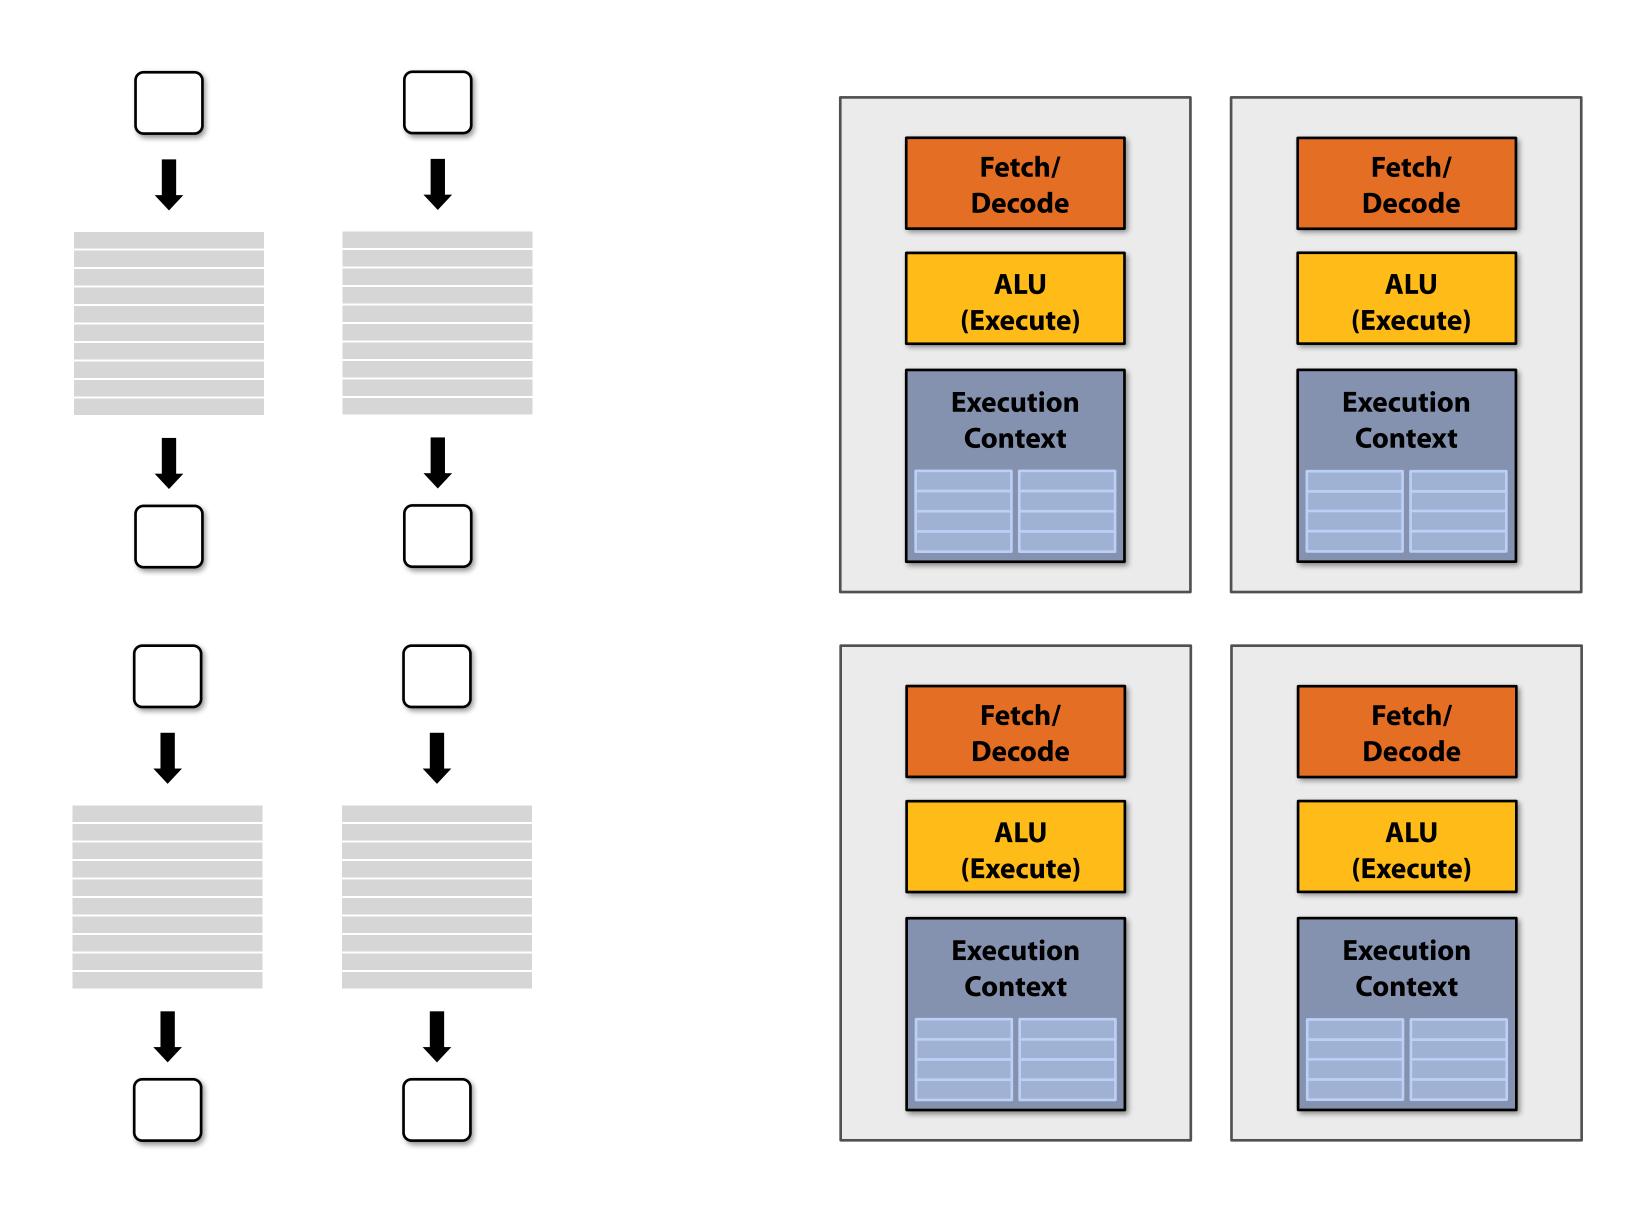

(in our fictitious data-parallel language)

```
void sinx(int N, int terms, float* x, float* result)
{
   // declare independent loop iterations
   forall (int i from 0 to N-1)
   {
      float value = x[i];
      float numer = x[i] * x[i] * x[i];
      int denom = 6; // 3!
      int sign = -1;
      for (int j=1; j<=terms; j++)</pre>
      {
         value += sign * numer / denom;
         numer *= x[i] * x[i];
         denom *= (2*j+2) * (2*j+3);
         sign *= -1;
      }
      result[i] = value;
```

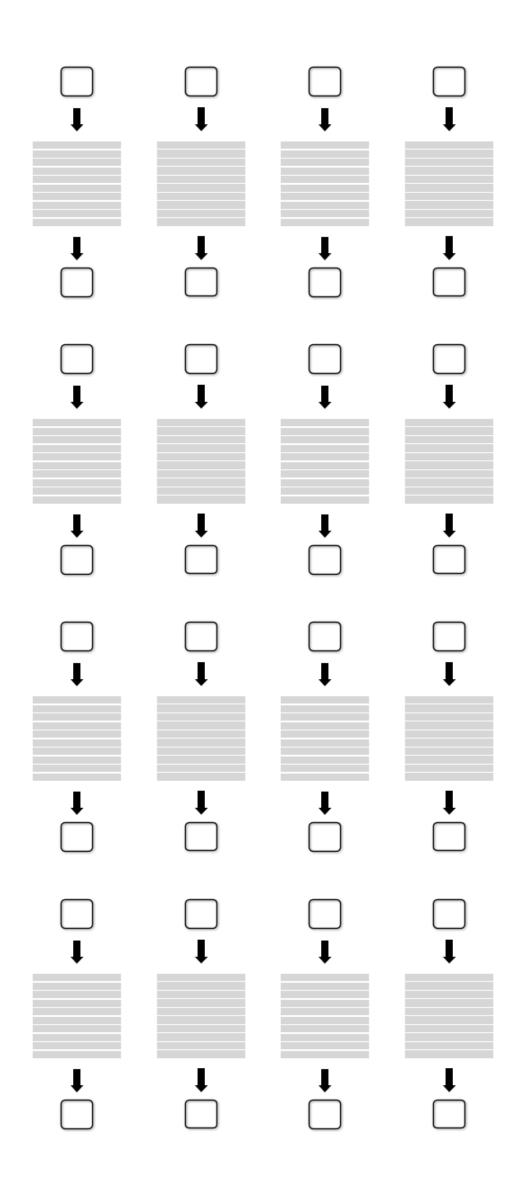

Loop iterations declared by the programmer to be independent

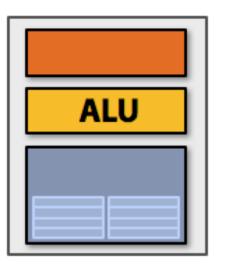

With this information, you could imagine how a compiler might automatically generate parallel threaded code

Four cores: compute four elements in parallel

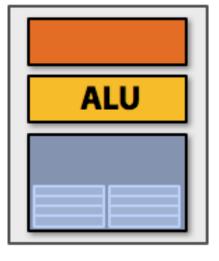

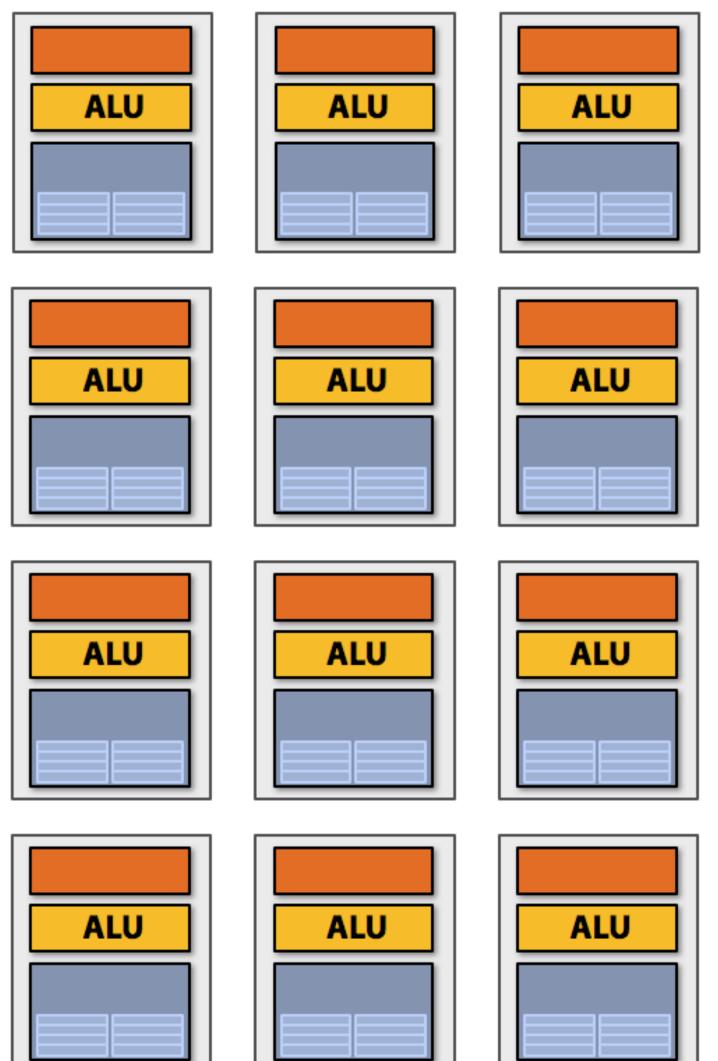

Sixteen cores: compute sixteen elements in parallel

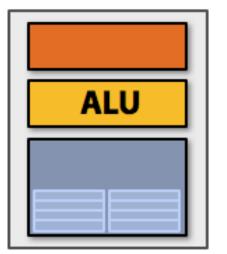

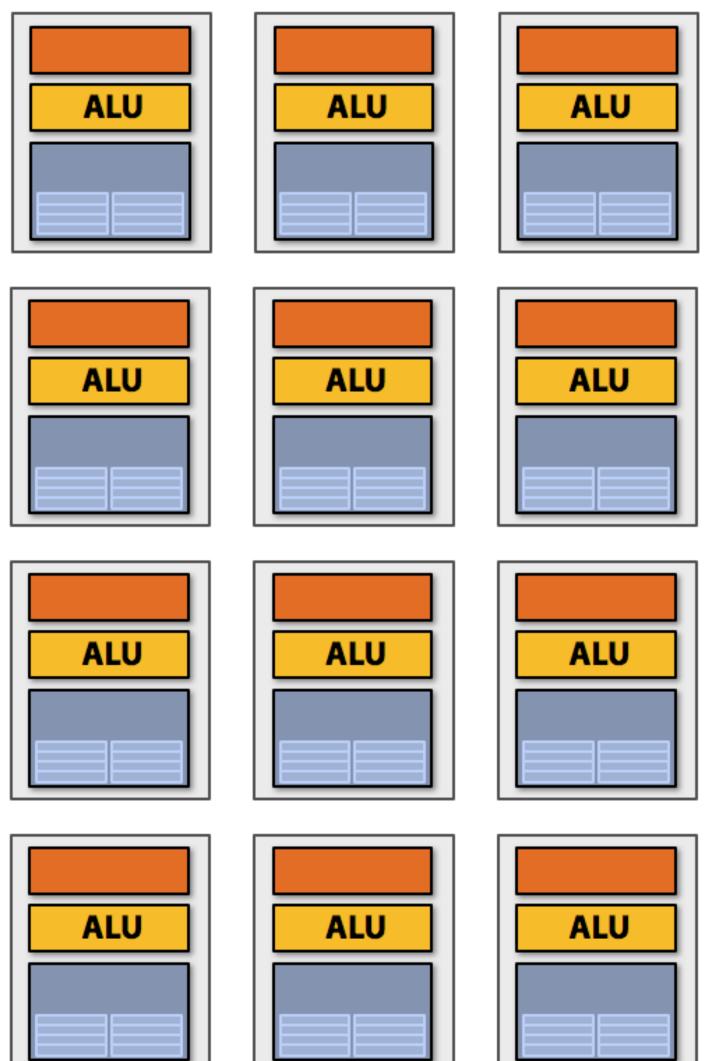

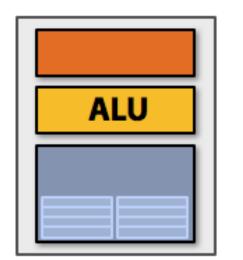

ALU

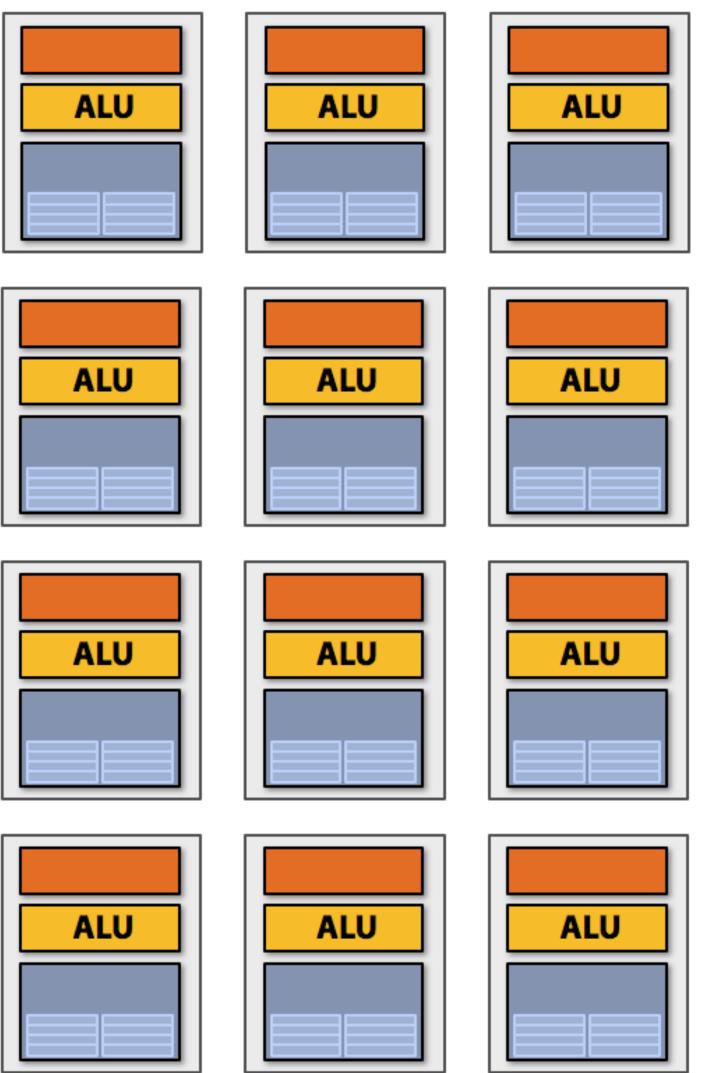

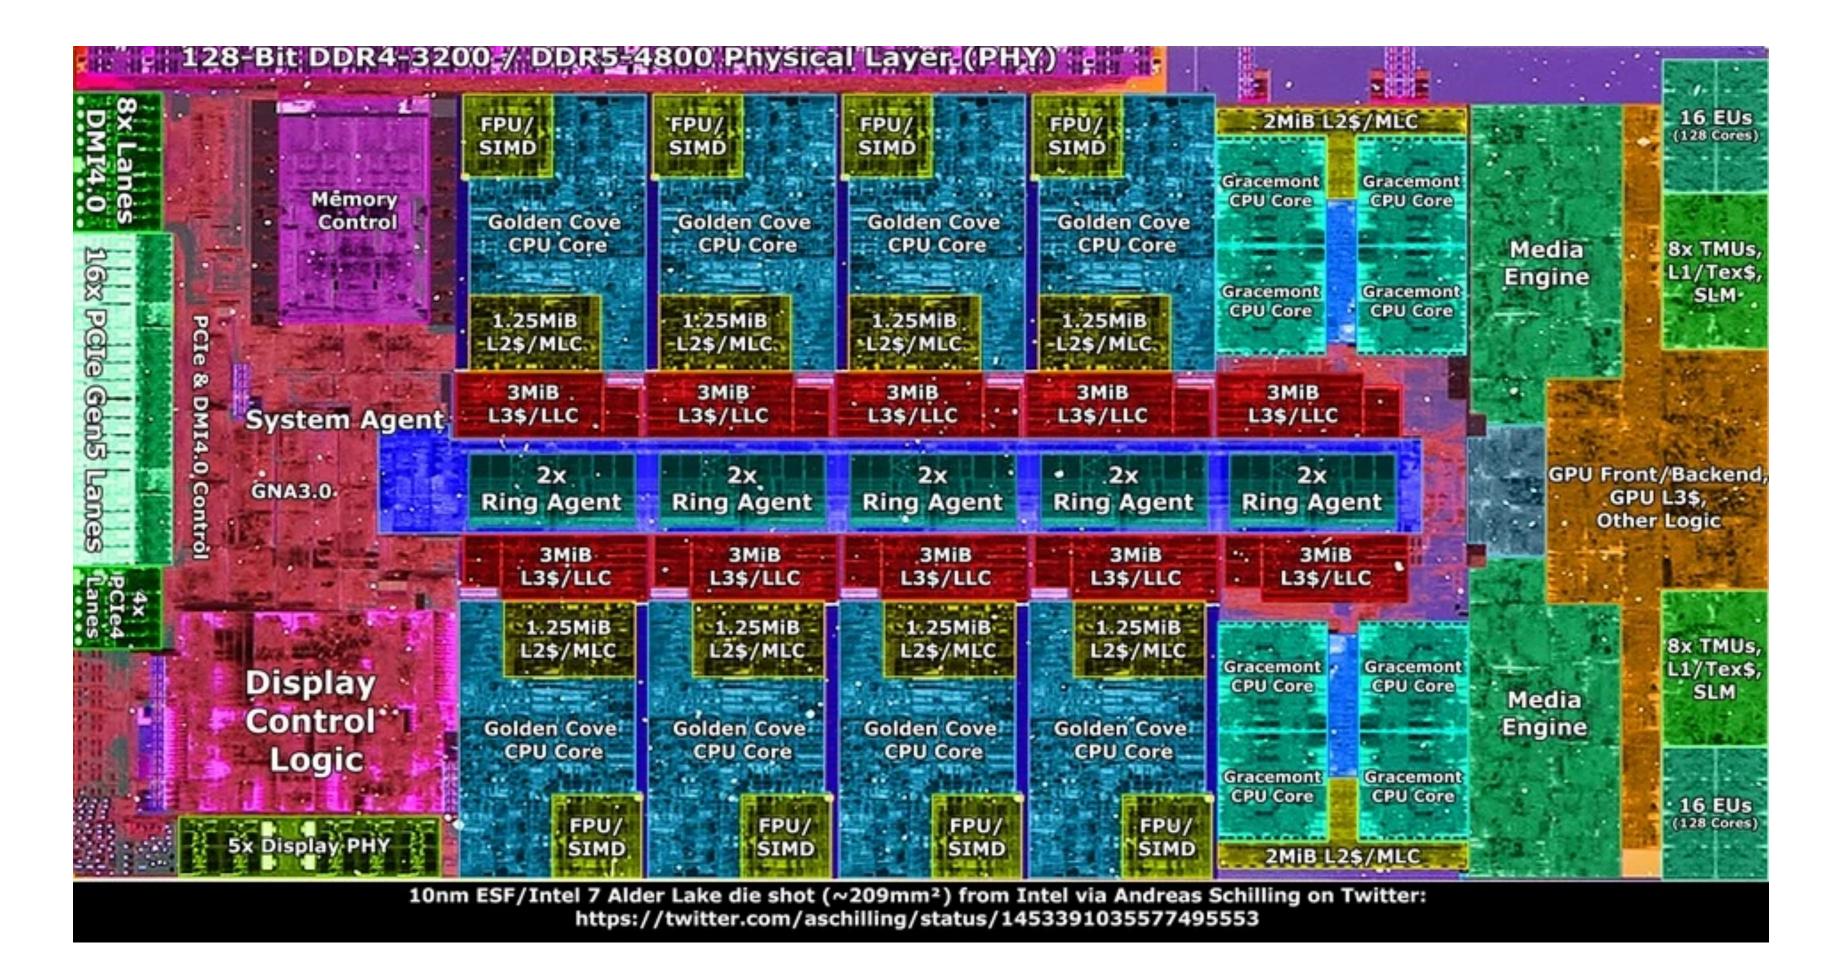

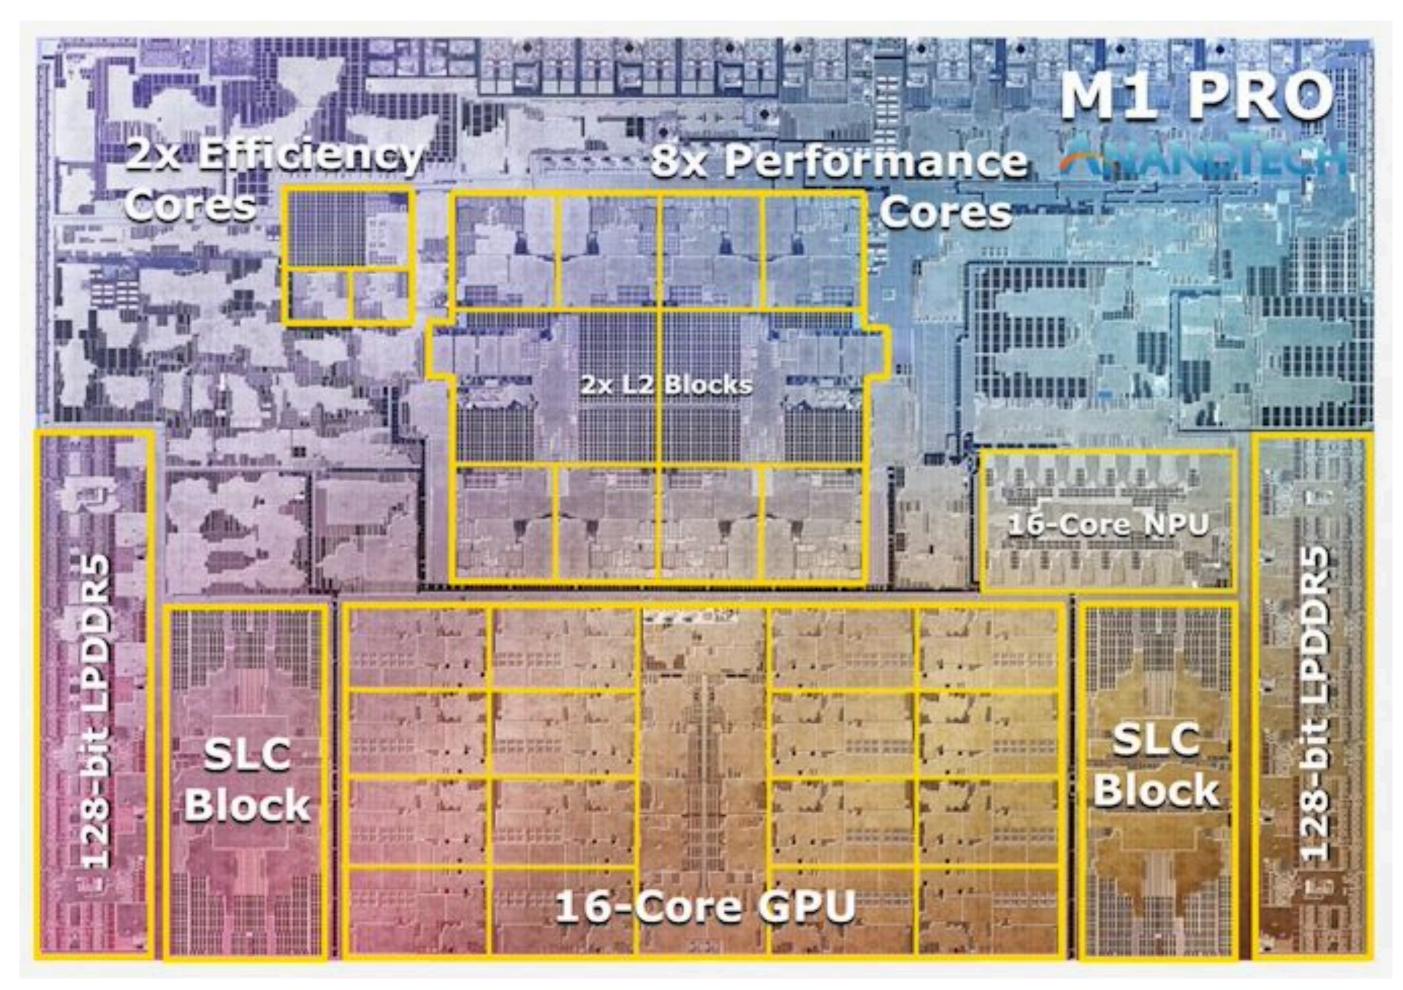

Sixteen cores, sixteen simultaneous instruction streams

Intel Alder Lake-S (2021)

16 CPU cores (8 performance + 8 efficiency)

Laptops: Apple M1 Pro (2021)

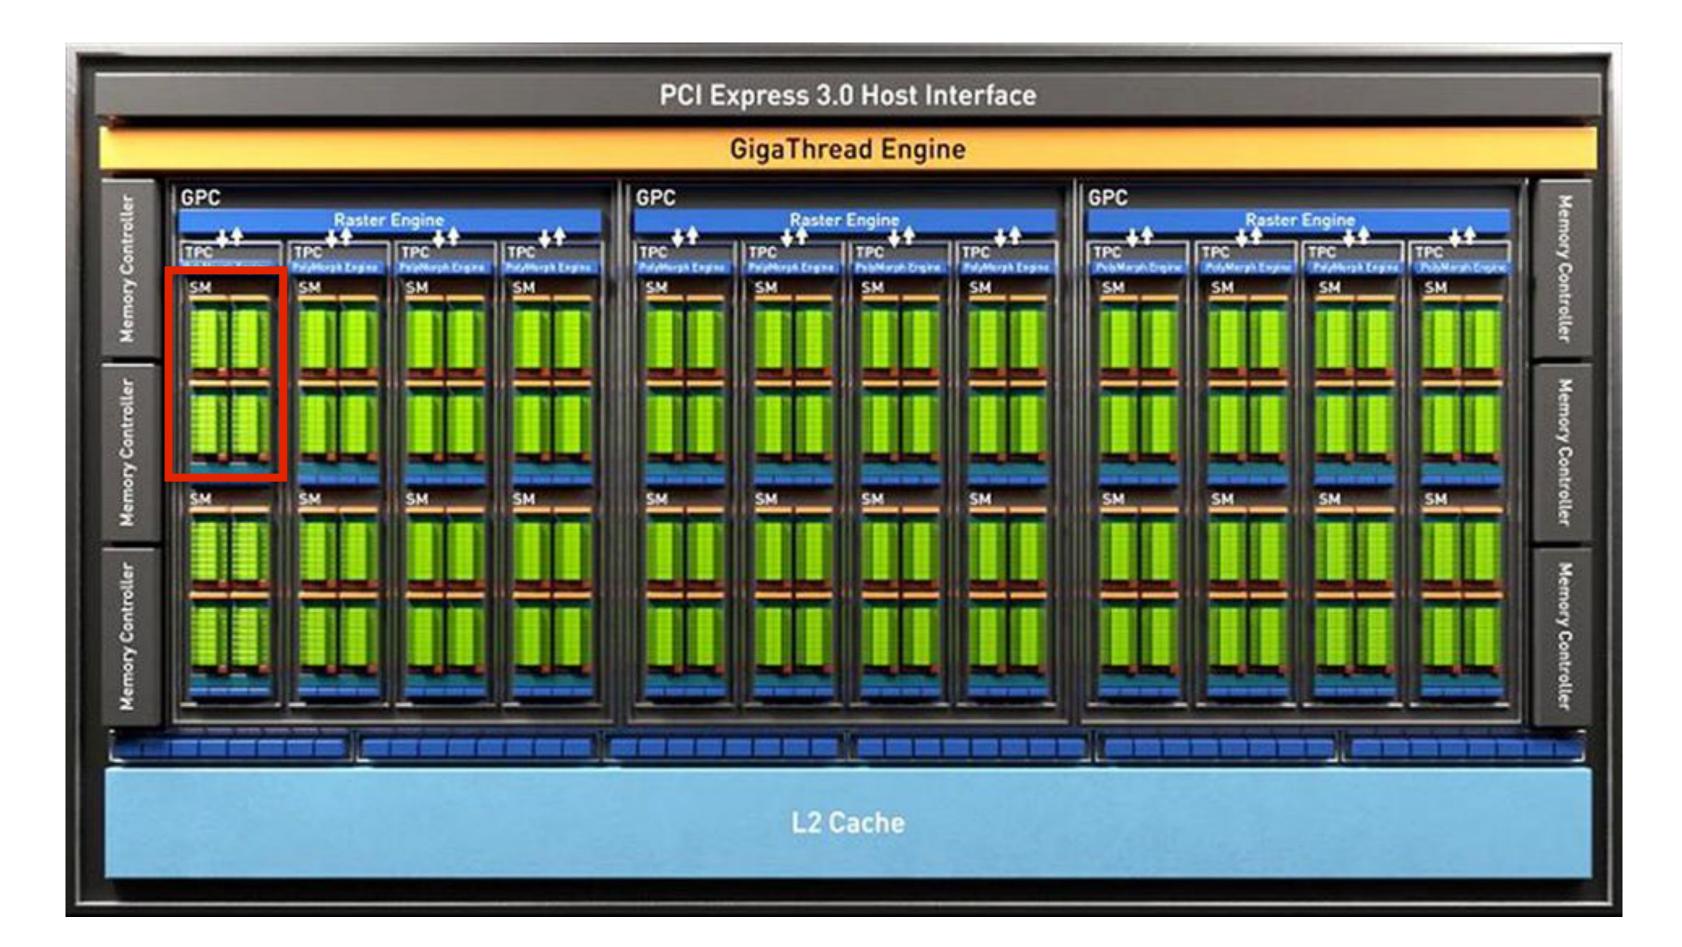

10 CPU Cores (8 performance + 2 efficiency)

16 GPU Cores

NVIDIA GeForce GTX 1660 Ti GPU (2019)

24 major processing blocks (1536 "CUDA cores")

Data-parallel expression

(in our fictitious data-parallel language)

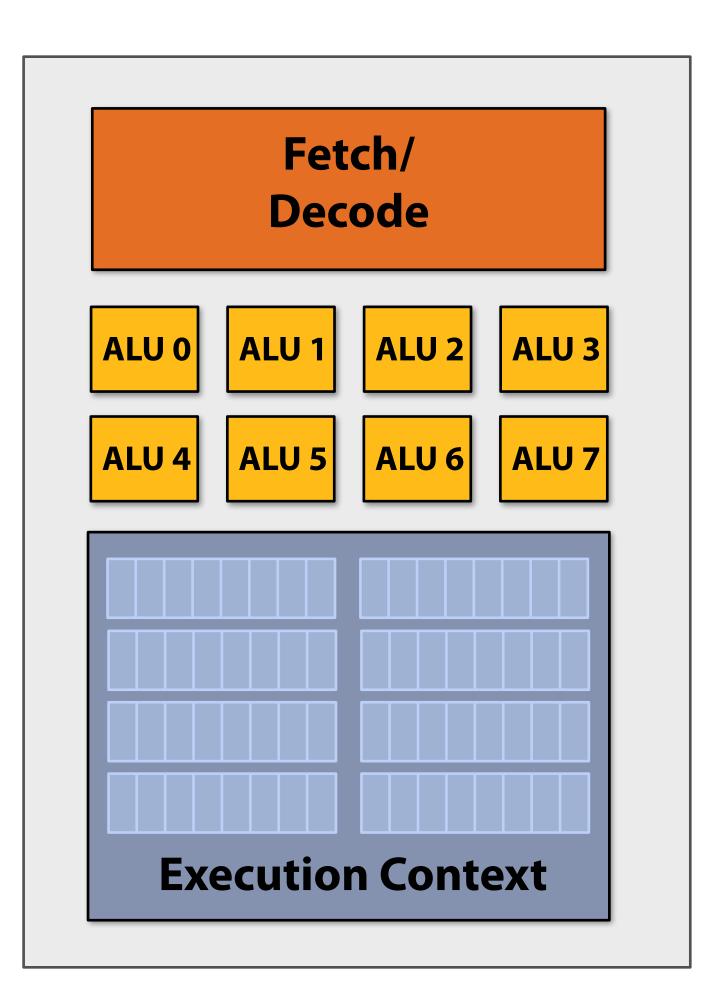

```
void sinx(int N, int terms, float* x, float* result)
{
   // declare independent loop iterations
   forall (int i from 0 to N-1)
   {
      float value = x[i];
      float numer = x[i] * x[i] * x[i];
      int denom = 6; // 3!
                                                          number
      int sign = -1;
      for (int j=1; j<=terms; j++)</pre>
      {
         value += sign * numer / denom;
         numer *= x[i] * x[i];
         denom *= (2*j+2) * (2*j+3);
         sign *= -1;
      }
      result[i] = value;
```

Another interesting property of this code:

Parallelism is across iterations of the loop.

All the iterations of the loop do the same thing: evaluate the sine of a single input number

Add ALUs to increase compute capability

Idea #2:

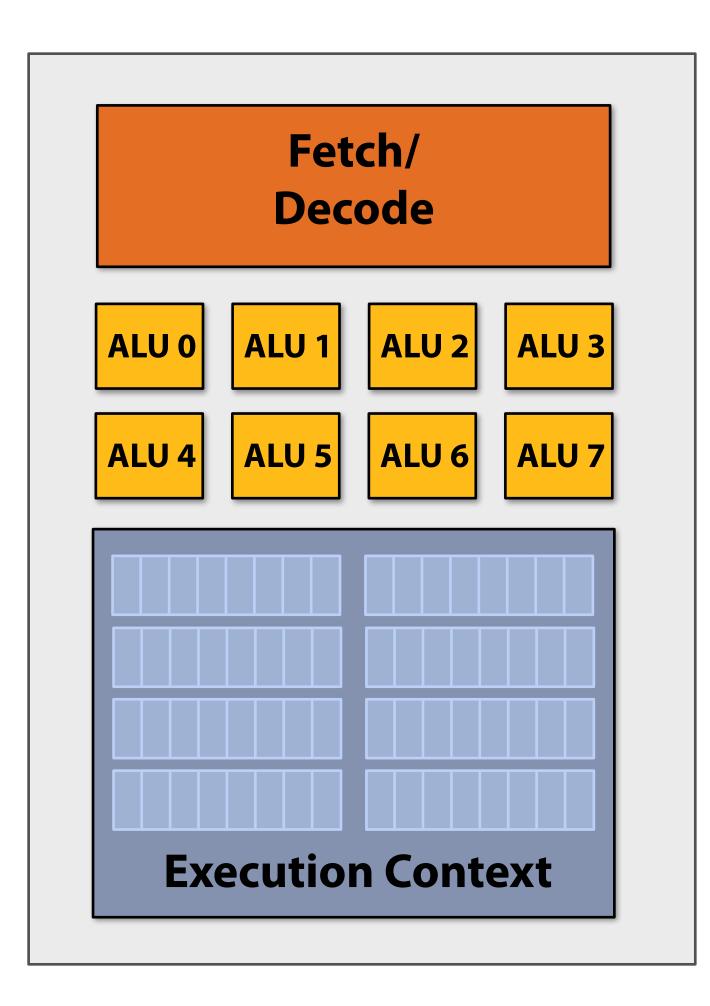

SIMD processing Single instruction, multiple data

Executed in parallel on all ALUs

Amortize cost/complexity of managing an instruction stream across many ALUs

Same instruction broadcast to all ALUs

Add ALUs to increase compute capability

ld	r0,	addı	r[r1]
mul	r1,	r0,	r0
mul	r1,	r1,	r0
• • •			
• • •			
• • •			
• • •			
• • •			
• • •			
st	addı	r[r2]], r0

registers (e.g., 32-bit floats)

Recall original compiled program:

Instruction stream processes one array element at a time using scalar instructions on scalar

Scalar program

```
void sinx(int N, int terms, float* x, float* result)
{
   for (int i=0; i<N; i++)</pre>
   {
      float value = x[i];
      float numer = x[i] * x[i] * x[i];
      int denom = 6; // 3!
      int sign = -1;
                                                                           ld
      for (int j=1; j<=terms; j++)</pre>
      {
                                                                           • • •
          value += sign * numer / denom;
                                                                           • • •
          numer *= x[i] * x[i];
                                                                           • • •
          denom *= (2*j+2) * (2*j+3);
                                                                           • • •
          sign *= -1;
                                                                           • • •
      }
                                                                           • • •
                                                                           st
      result[i] = value;
   }
```

Original compiled program: Processes one array element using scalar instructions on scalar registers (e.g., 32-bit floats)

ld r0, addr[r1]
mul r1, r0, r0
mul r1, r1, r0
...
...
...
...
st addr[r2], r0

Vector program (using AVX intrinsics)

```
#include <immintrin.h>
void sinx(int N, int terms, float* x, float* result)
{
   float three_fact = 6: // 3!
   for (int i=0; i<N; i+=8)</pre>
   {
       ___m256 origx = _mm256_load_ps(&x[i]);
      __m256 value = origx;
      __m256 numer = _mm256_mul_ps(origx, _mm256_mul_ps(origx, origx));
      __m256 denom = _mm256_broadcast_ss(&three_fact);
      int sign = -1;
      for (int j=1; j<=terms; j++)</pre>
      {
         // value += sign * numer / denom
         __m256 tmp = _mm256_div_ps(_mm256_mul_ps(_mm256_set1ps(sign), numer), denom);
         value = _mm256_add_ps(value, tmp);
         numer = _mm256_mul_ps(numer, _mm256_mul_ps(origx, origx));
         denom = _mm256_mul_ps(denom, _mm256_broadcast_ss((2*j+2) * (2*j+3)));
         sign *= -1;
      }
      mm256 store ps(&result[i], value);
   }
}
```

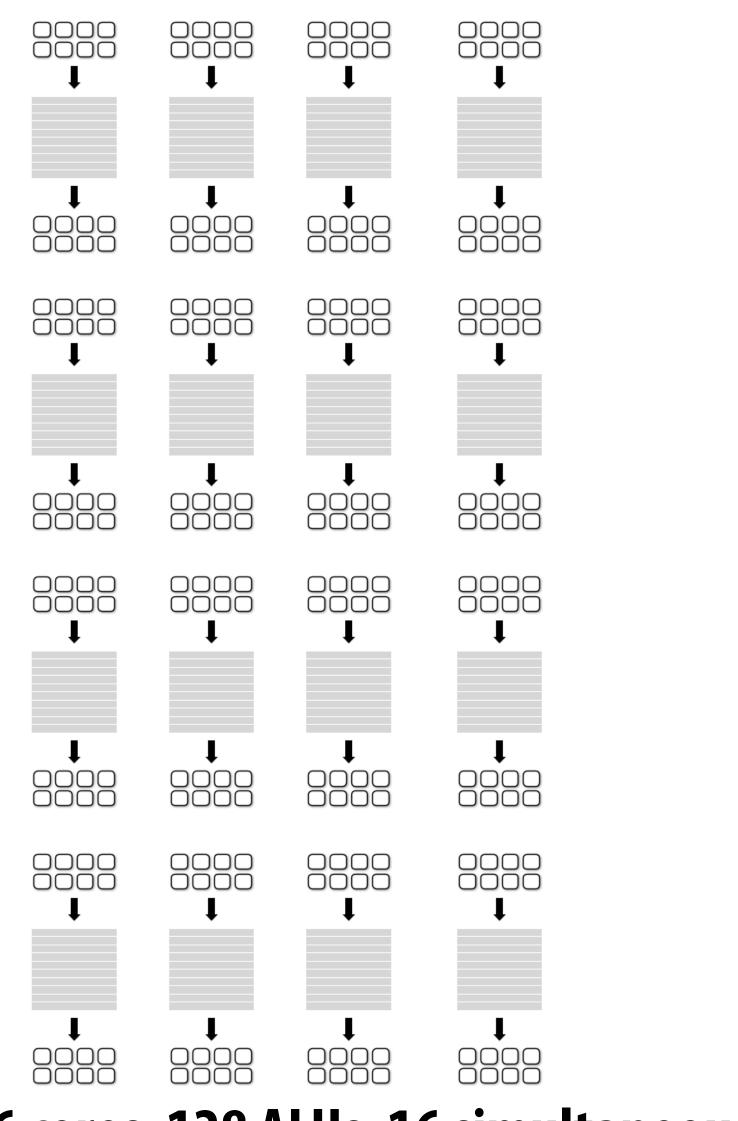

Intrinsics available to C programmers

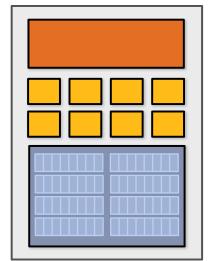

Vector program (using AVX intrinsics)

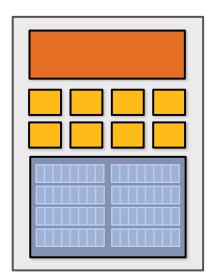

```
#include <immintrin.h>
void sinx(int N, int terms, float* x, float* sinx)
{
   float three_fact = 6; // 3!
   for (int i=0; i<N; i+=8)</pre>
   {
       __m256 origx = _mm256_load_ps(&x[i]);
       <u>___</u>m256 value = origx;
       __m256 numer = _mm256_mul_ps(origx, _mm256_mul_ps(origx, origx));
       __m256 denom = _mm256_broadcast_ss(&three_fact);
      int sign = -1;
      for (int j=1; j<=terms; j++)</pre>
      {
         // value += sign * numer / denom
          __m256 tmp = _mm256_div_ps(_mm256_mul_ps(_mm256_broadcast_ss(sign),numer),denom);
          value = _mm256_add_ps(value, tmp);
          numer = _mm256_mul_ps(numer, _mm256_mul_ps(origx, origx));
          denom = _mm256_mul_ps(denom, _mm256_broadcast_ss((2*j+2) * (2*j+3)));
          sign *= -1;
       _mm256_store_ps(&sinx[i], value);
}

16 SIMD cores: 128 elements in parallel

			Ì		
	L				

16 cores, 128 ALUs, 16 simultaneous instruction streams

Data-parallel expression

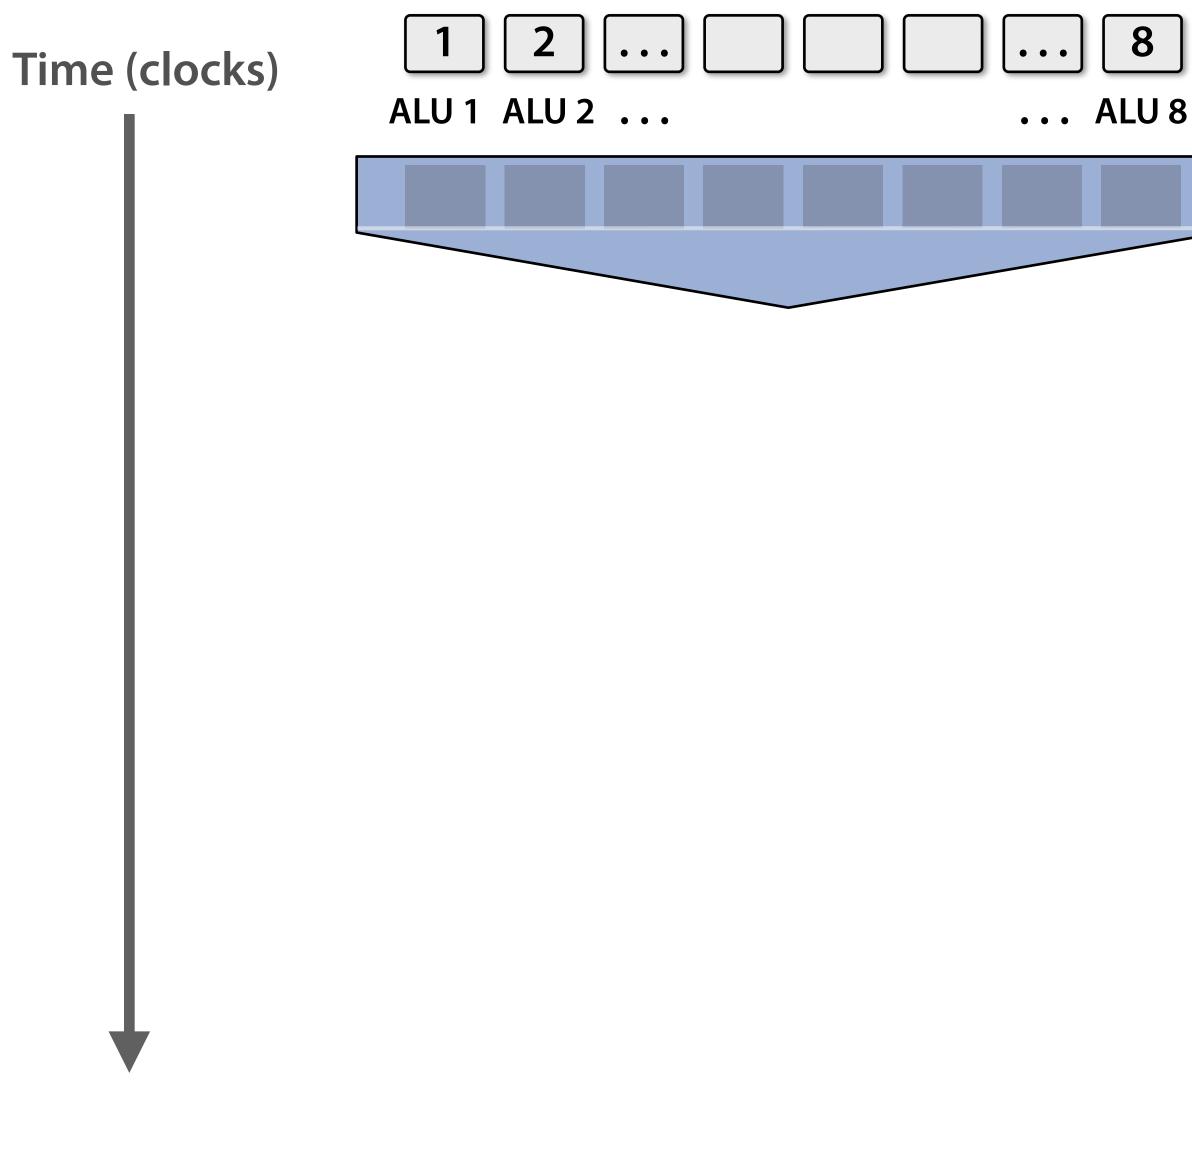

(in our fictitious data-parallel language)

```
void sinx(int N, int terms, float* x, float* result)
{
   // declare independent loop iterations
   forall (int i from 0 to N-1)
   {
      float value = x[i];
      float numer = x[i] * x[i] * x[i];
      int denom = 6; // 3!
      int sign = -1;
      for (int j=1; j<=terms; j++)</pre>
      {
         value += sign * numer / denom
         numer *= x[i] * x[i];
         denom *= (2*j+2) * (2*j+3);
         sign *= -1;
      }
      result[i] = value;
```

Compiler understands loop iterations are independent, and that same loop body will be executed on a large number of data elements.

Abstraction facilitates automatic generation of <u>both</u> multi-core parallel code, and vector instructions to make use of SIMD processing capabilities within a core.

What about conditional execution?

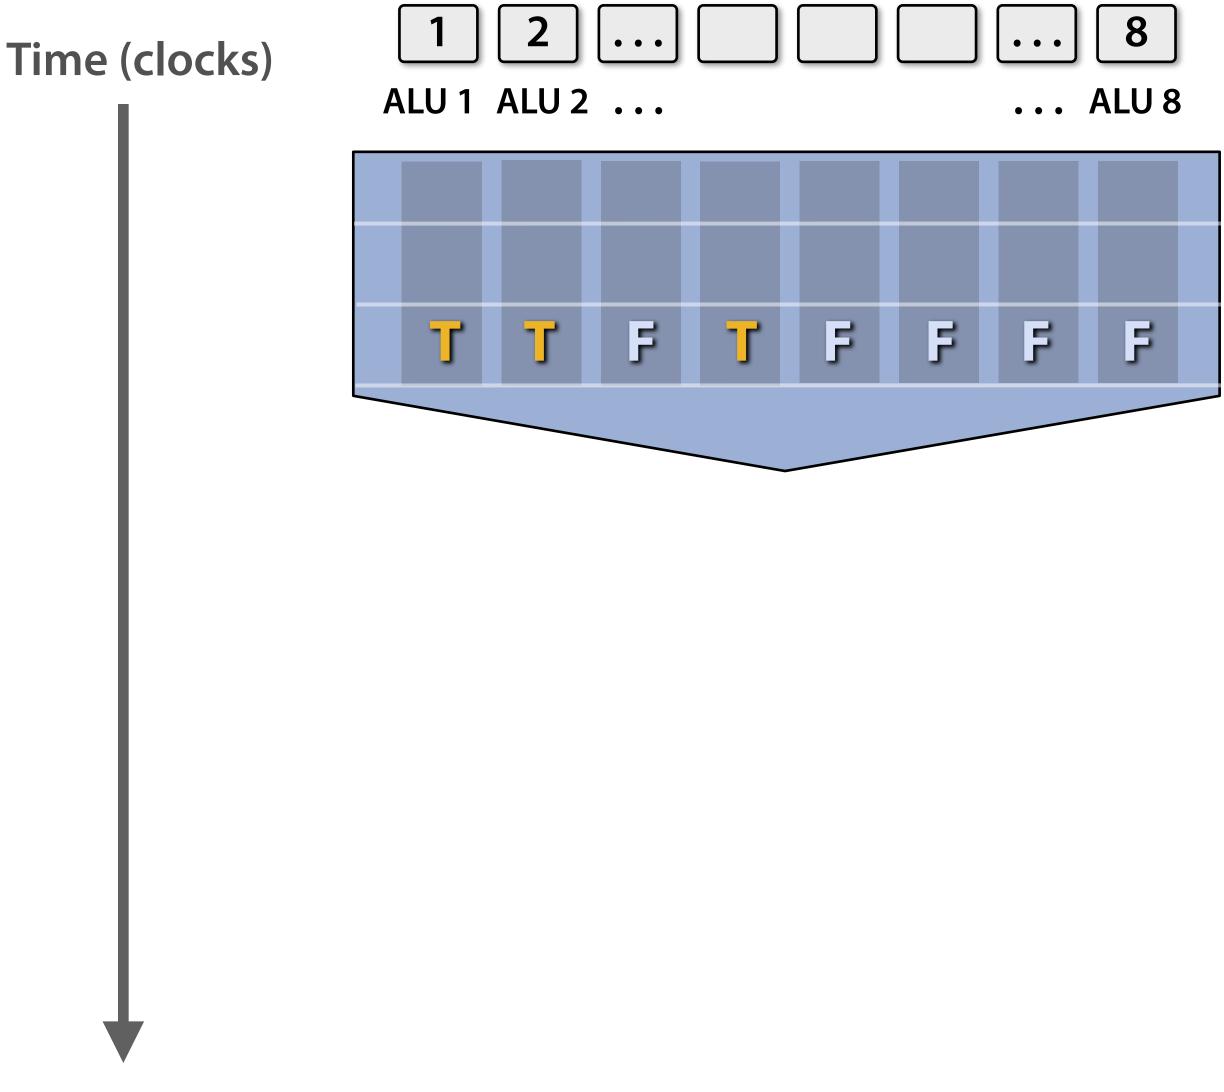

<unconditional code> float x = A[i]; if (x > 0) { float tmp = exp(x,5.f); tmp *= kMyConst1; x = tmp + kMyConst2; } else { float tmp = kMyConst1; x = 2.f * tmp;} <resume unconditional code> result[i] = x;

(assume logic below is to be executed for each

the array 'result')

element in input array 'A', producing output into

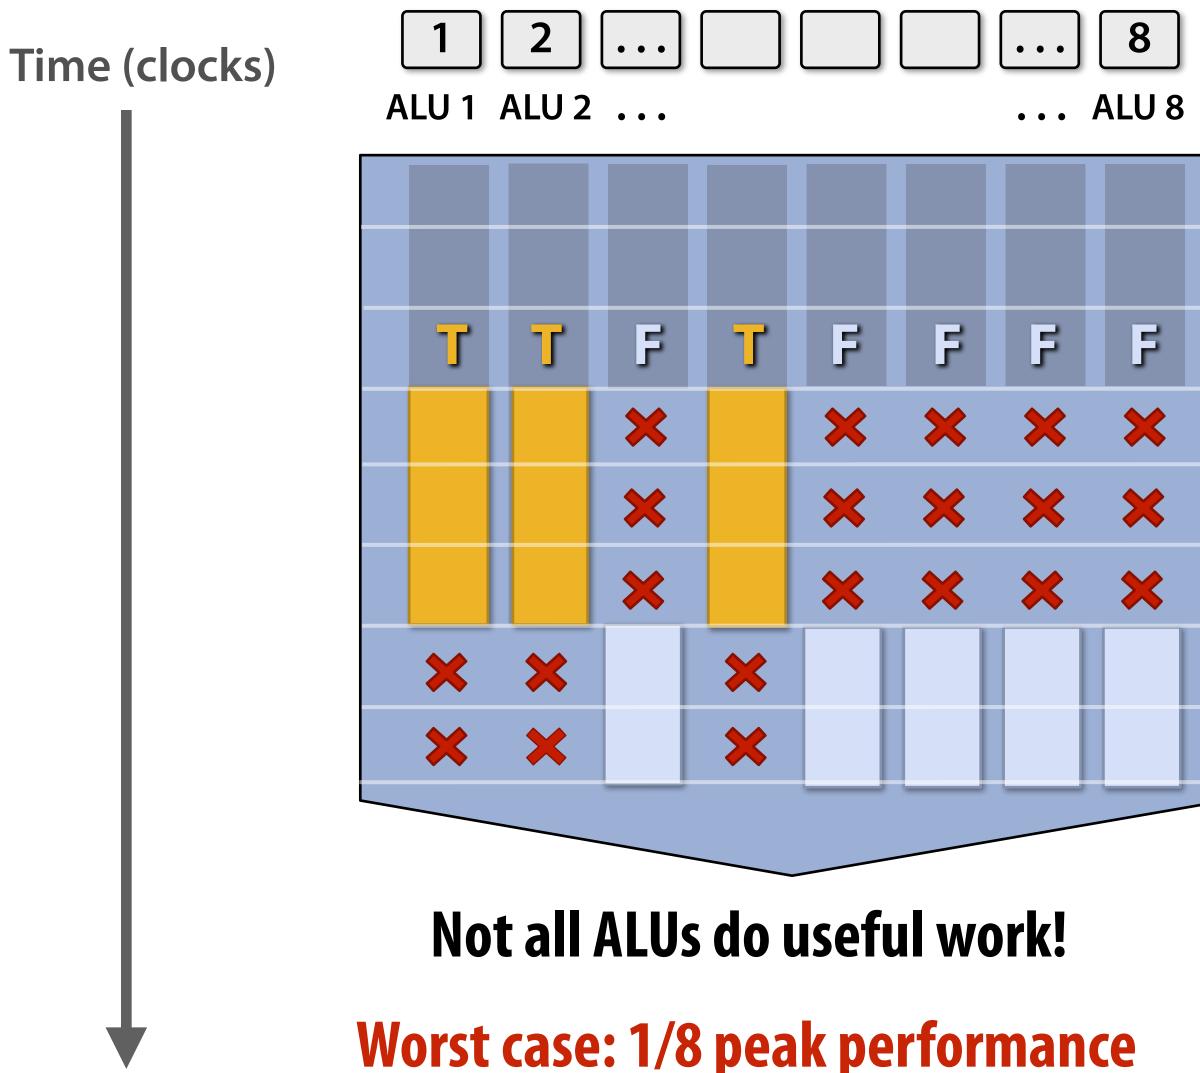

What about conditional execution?

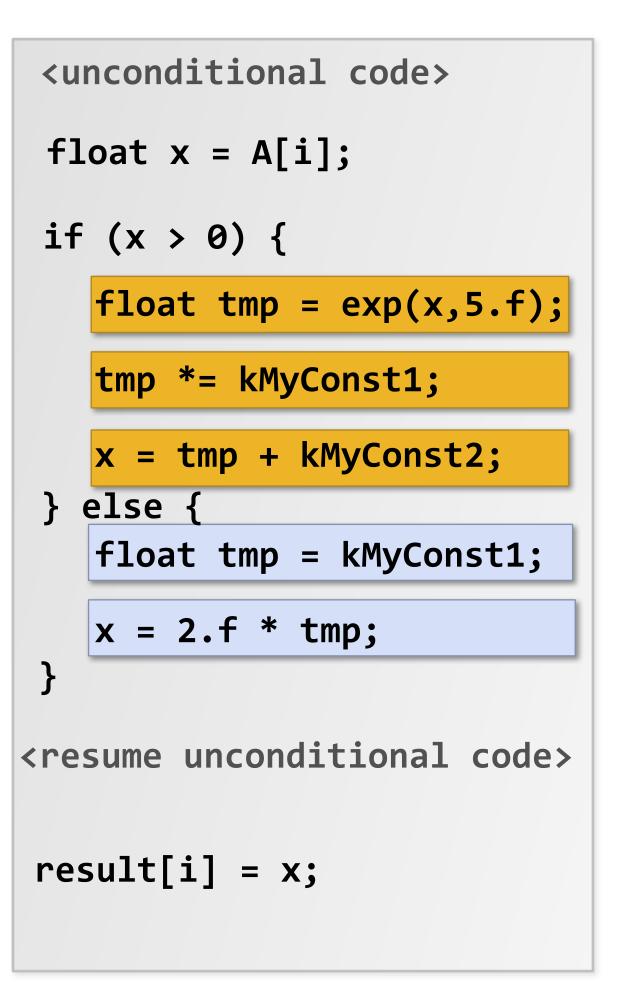

(assume logic below is to be executed for each element in input array 'A', producing output into the array 'result')

```
<unconditional code>
 float x = A[i];
 if (x > 0) {
   float tmp = exp(x,5.f);
   tmp *= kMyConst1;
   x = tmp + kMyConst2;
} else {
   float tmp = kMyConst1;
   x = 2.f * tmp;
}
<resume unconditional code>
result[i] = x;
```

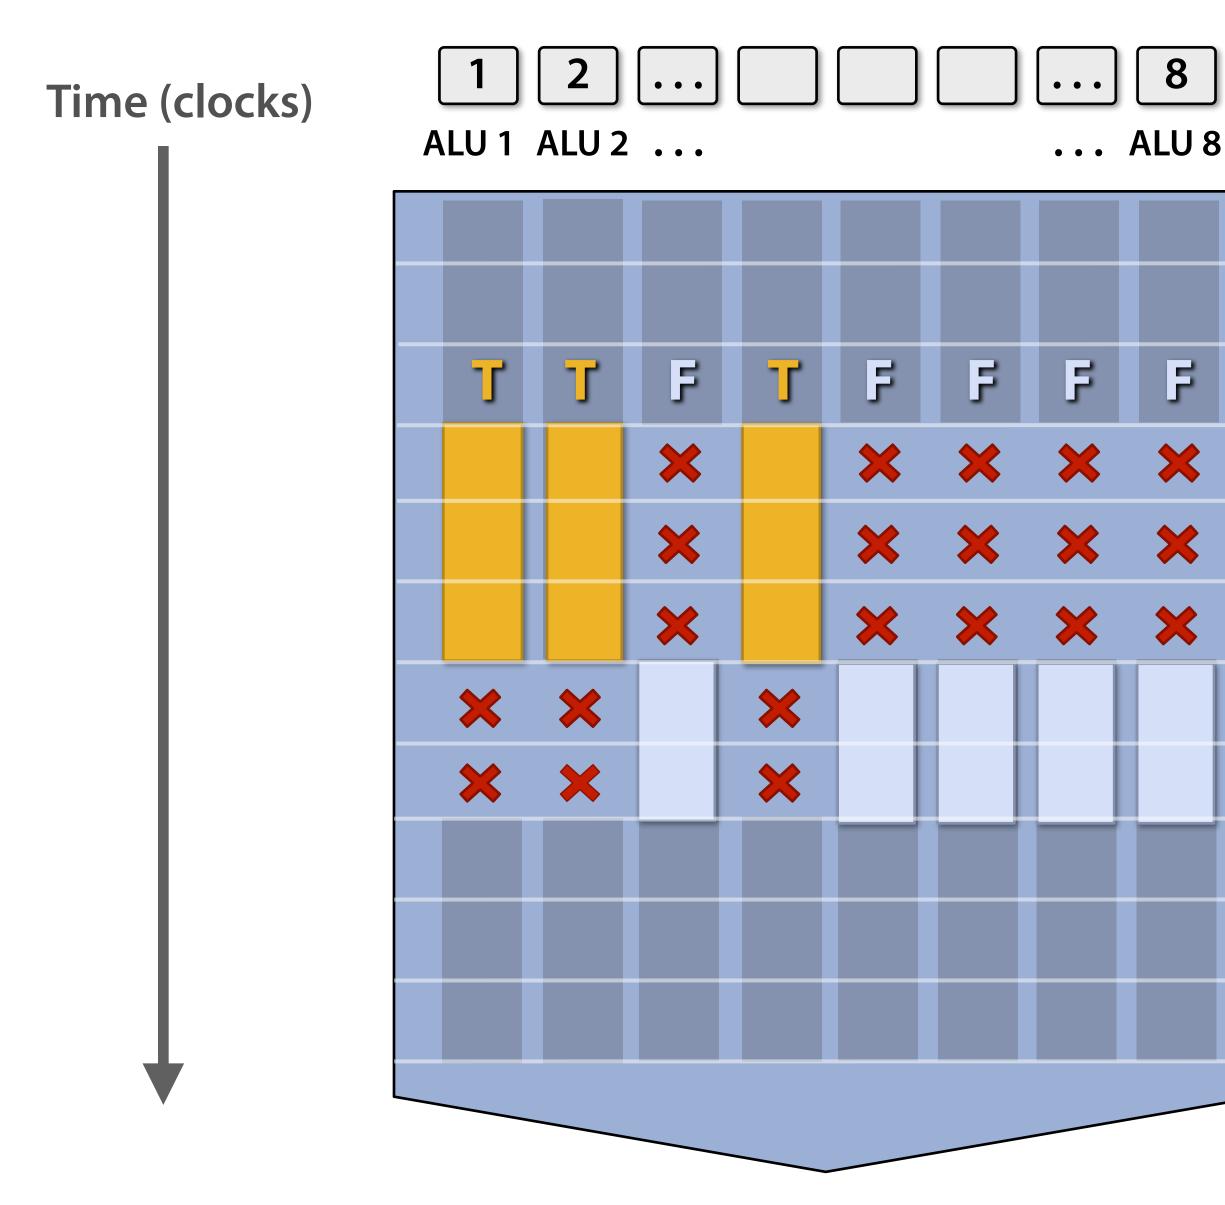

Mask (discard) output of ALU

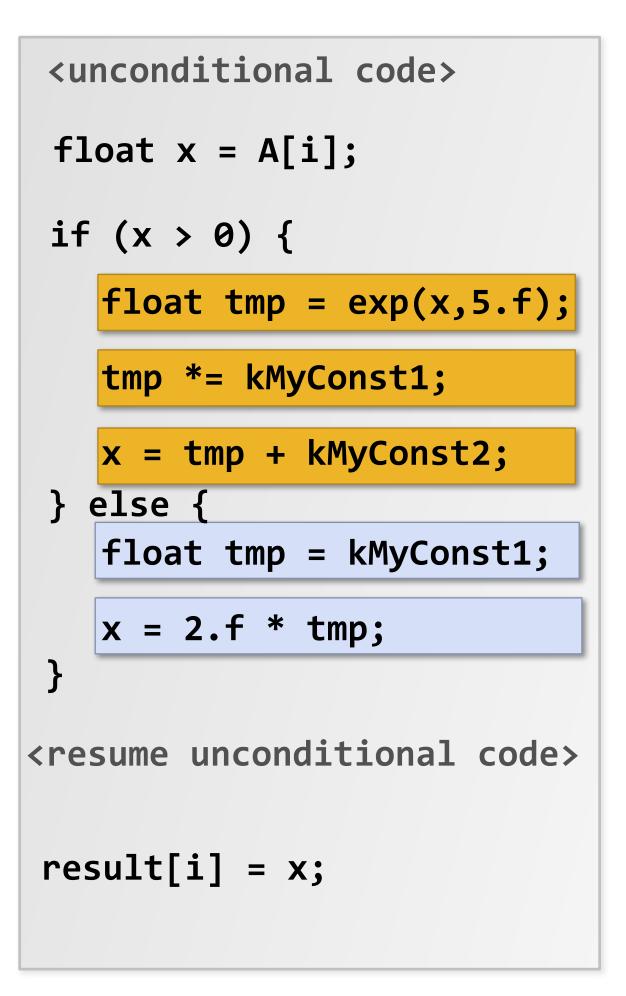

(assume logic below is to be executed for each element in input array 'A', producing output into the array 'result')

After branch: continue at full performance

(assume logic below is to be executed for each element in input array 'A', producing output into the array 'result')

Terminology

- Instruction stream coherence
 - Same instruction sequence applies to all elements operated upon simultaneously
 - **Coherent execution is necessary for efficient use of SIMD processing resources**
 - Coherent execution IS NOT necessary for efficient parallelization across cores, since each core has the capability to fetch/decode a different instruction stream
- "Divergent" execution
 - A lack of instruction stream coherence
- Note: don't confuse instruction stream coherence with "cache coherence" (a major topic later in the course)

("coherent execution")

SIMD execution on modern CPUs

- SSE instructions: 128-bit operations: 4x32 bits or 2x64 bits (4-wide float vectors)
- AVX instructions: 256 bit operations: 8x32 bits or 4x64 bits (8-wide float vectors)
- Instructions are generated by the compiler
 - Parallelism explicitly requested by programmer using intrinsics
 - Parallelism conveyed using parallel language semantics (e.g., forall example)
 - Parallelism inferred by dependency analysis of loops (hard problem, even best compilers are not great on arbitrary C/C++ code)
- Terminology: "explicit SIMD": SIMD parallelization is performed at compile time
 - Can inspect program binary and see instructions (vstoreps, vmulps, etc.)

SIMD execution on many modern GPUs

- "Implicit SIMD"
 - **Compiler generates a scalar binary (scalar instructions)**
 - But N instances of the program are *always run* together on the processor execute(my_function, N) // execute my_function N times
 - In other words, the interface to the hardware itself is data-parallel
 - Hardware (not compiler) is responsible for simultaneously executing the same instruction from multiple instances on different data on SIMD ALUs
- SIMD width of most modern GPUs ranges from 8 to 32
 - Divergence can be a big issue (poorly written code might execute at 1/32 the peak capability of the machine!)

Example: Intel Core i9 (Coffee Lake)

8 cores 8 SIMD ALUs per core (AVX2 instructions)

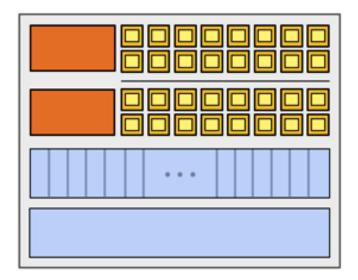

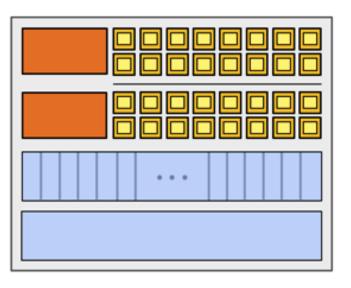

GHC machines:4 cores8 SIMD ALUs per core

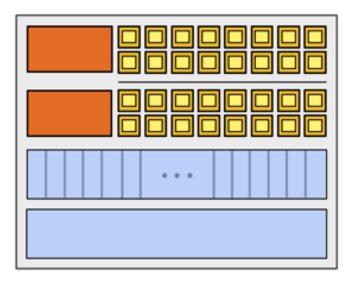

Machines in GHC 5207: (old GHC 3000 machines) 6 cores 4 SIMD ALUs per core

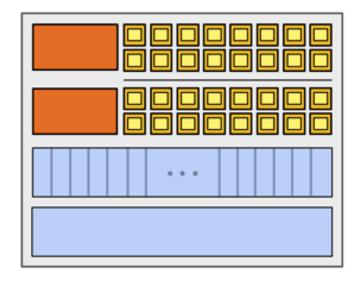

CPUs in "latedays" cluster: 6 cores 8 SIMD ALUs per code

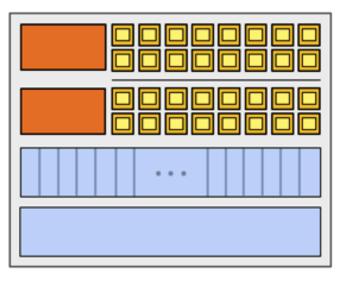

Example: NVIDIA GTX 480

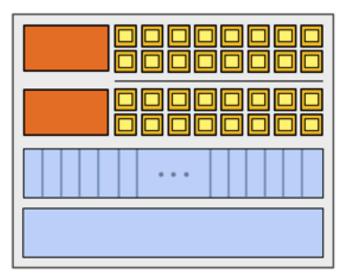

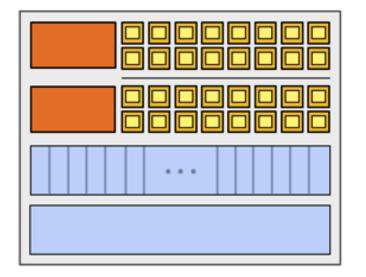

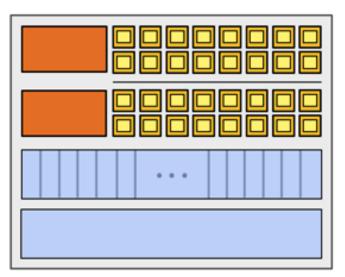

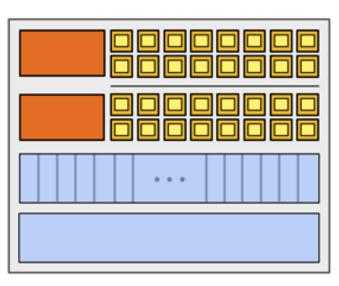

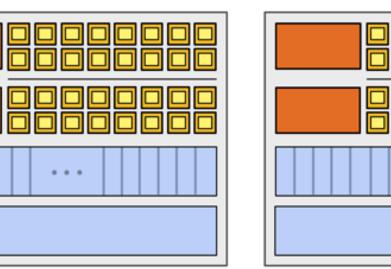

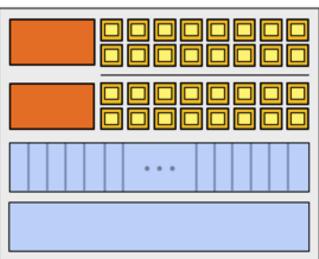

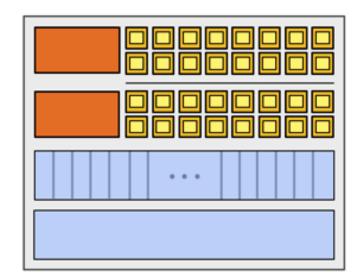

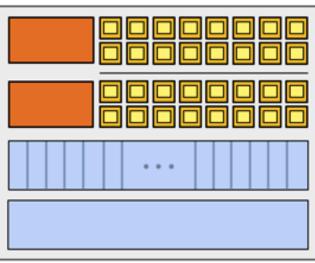

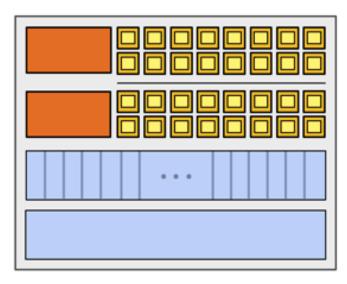

(in the Gates 5 lab)

15 cores32 SIMD ALUs per core1.3 TFLOPS

Summary: parallel execution

Several forms of parallel execution in modern processors

- Multi-core: use multiple processing cores
 - Provides thread-level parallelism: simultaneously execute a completely different instruction stream on each core
 - Software decides when to create threads (e.g., via pthreads API)
- SIMD: use multiple ALUs controlled by same instruction stream (within a core)
 - Efficient design for data-parallel workloads: control amortized over many ALUs
 - Vectorization can be done by compiler (explicit SIMD) or at runtime by hardware
 - [Lack of] dependencies is known prior to execution (usually declared by programmer, but can be inferred by loop analysis by advanced compiler)
- Superscalar: exploit ILP within an instruction stream. Process different instructions from the <u>same</u> instruction stream in parallel (within a core)
 - Parallelism automatically and dynamically discovered by the hardware during execution (not programmer visible) Not addressed further in this class. That's for a proper computer architecture design course like 18-447.

Quiz Time

L2 Participation Quiz on Canvas

Part 2: accessing memory

Terminology

Memory latency

- The amount of time for a memory request (e.g., load, store) from a processor to be serviced by the memory system
- Example: 100 cycles, 100 nsec
- Memory bandwidth
 - The rate at which the memory system can provide data to a processor
 - Example: 20 GB/s

DEMO Bandwidth vs Latency

Will need a few volunteers

Real World Example

What if we have to move exabytes of data?

Problem:

- Move X bytes of data
- From datacenter in Pittsburgh to New York
- 100 PB
 - 1e+11B/25mb/s = 1.1 hours
 - **1 EB**
 - 1e+18B/25 mb/s = 1,267 years

370 miles ~ 6.5 Hours

AWS Snowmobile

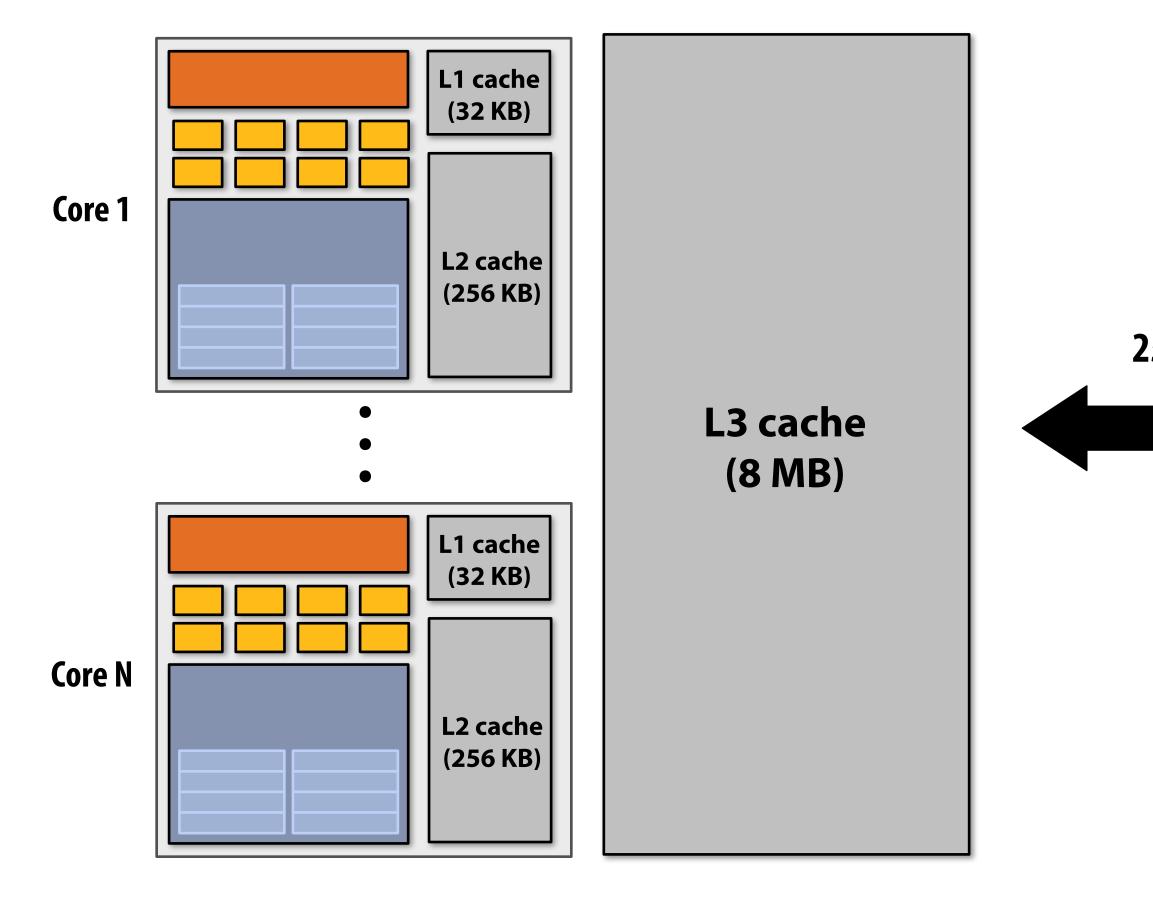

Stalls

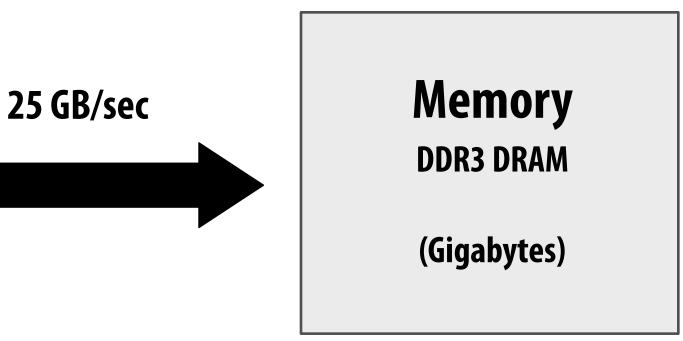

- A processor "stalls" when it cannot run the next instruction in an instruction stream because of a dependency on a previous instruction.
- Accessing memory is a major source of stalls

ld r0 mem[r2]
ld r1 mem[r3]
Dependency: cannot execute 'add' instruction until data at mem[r2] and
mem[r3] have been loaded from memory

- Memory access times ~ 100's of cycles
 - Memory "access time" is a measure of latency

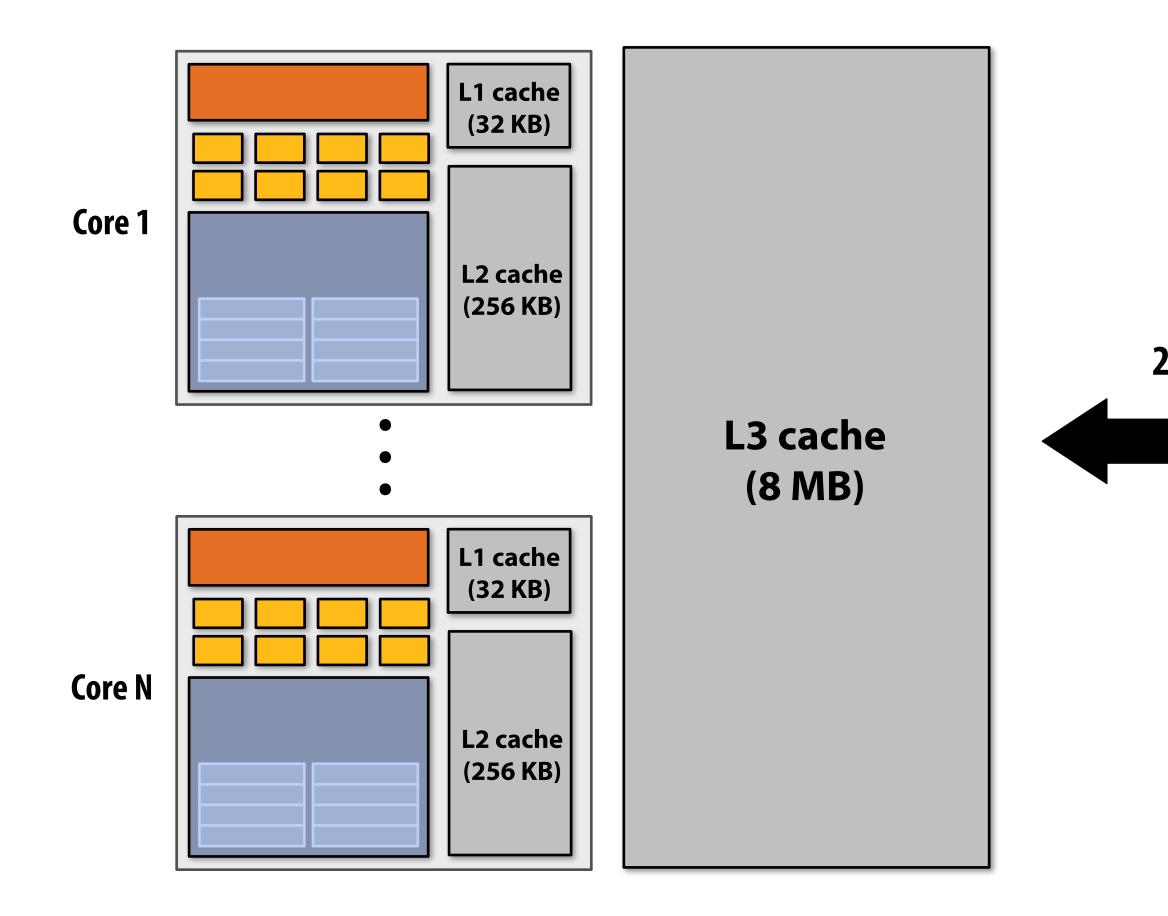

Review: why do processors have caches?

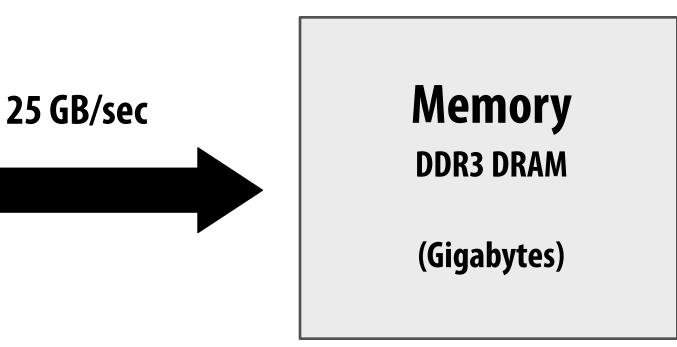

Caches reduce length of stalls (reduce latency)

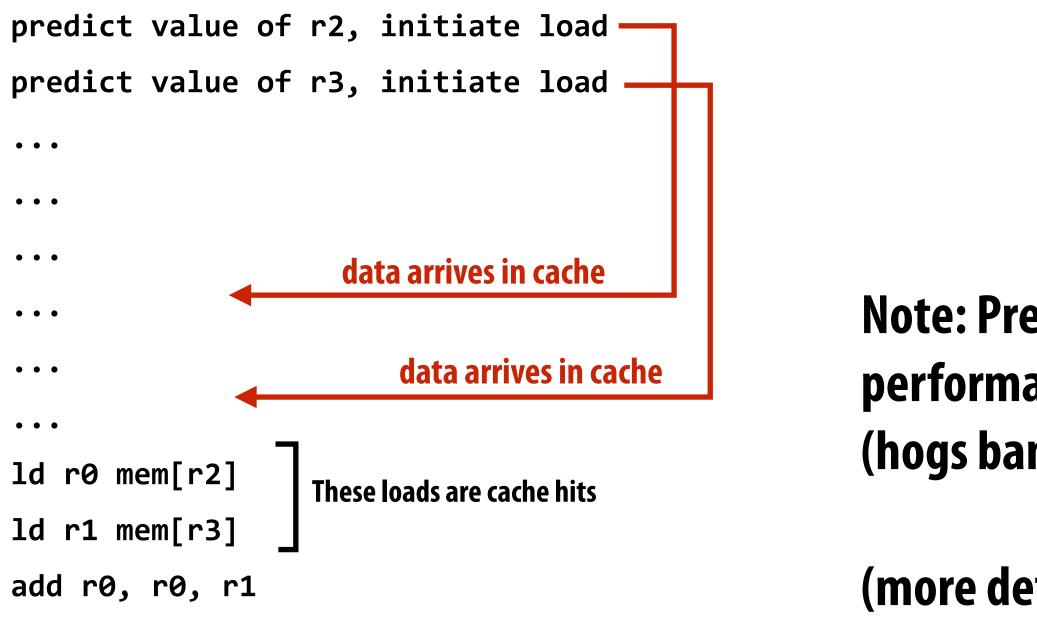

Processors run efficiently when data is resident in caches **Caches reduce memory access latency ***

* Caches also provide high bandwidth data transfer to CPU

Prefetching reduces stalls (<u>hides</u> latency) All modern CPUs have logic for prefetching data into caches Dynamically analyze program's access patterns, predict what it will access soon **Reduces stalls since data is resident in cache when accessed**

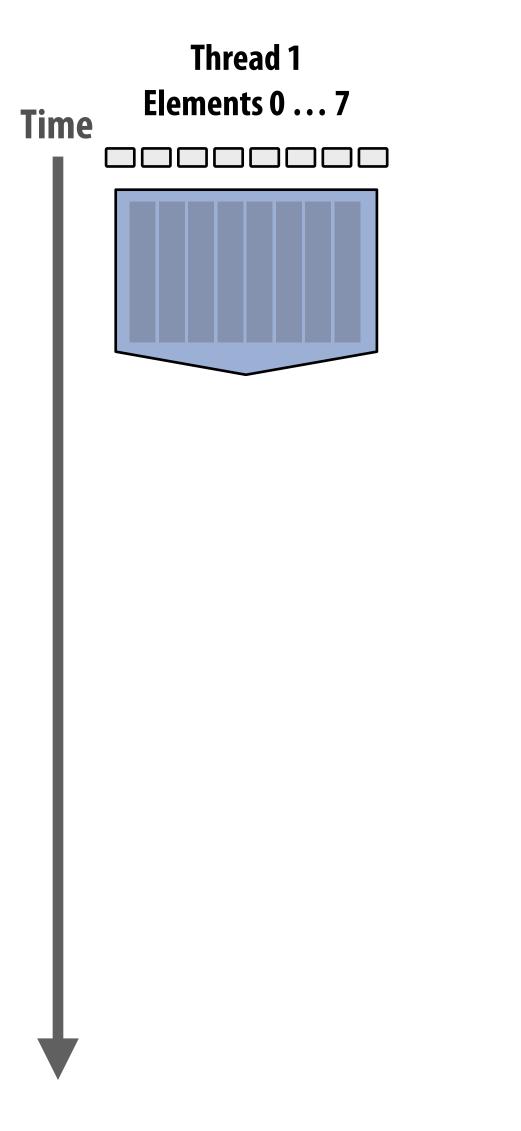

Note: Prefetching can also reduce performance if the guess is wrong (hogs bandwidth, pollutes caches)

(more detail later in course)

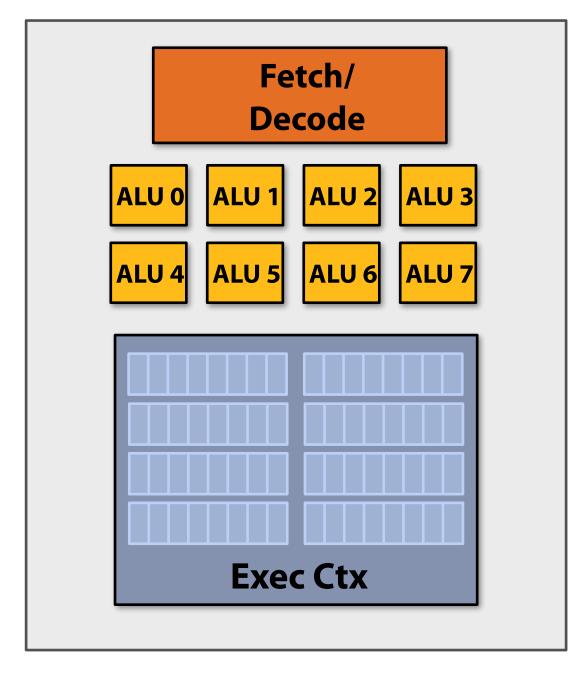

Multi-threading reduces stalls

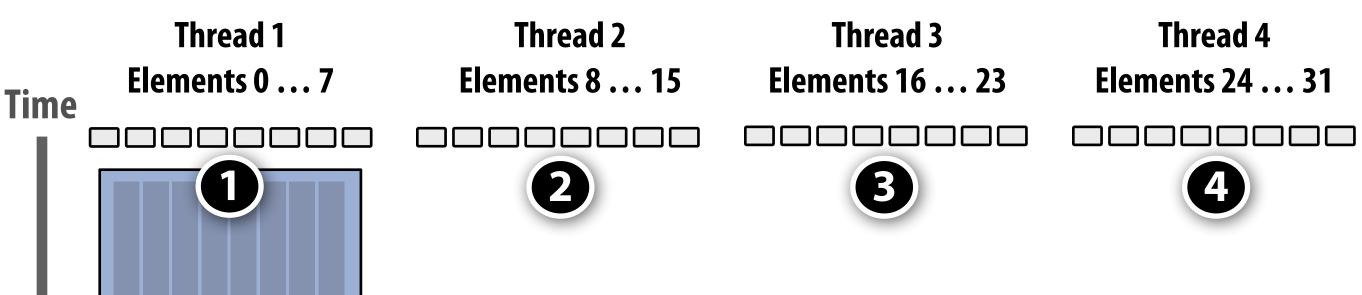

- Idea: <u>interleave</u> processing of multiple threads on the same core to hide stalls
- Like prefetching, multi-threading is a latency <u>hiding</u>, not a latency <u>reducing</u> technique

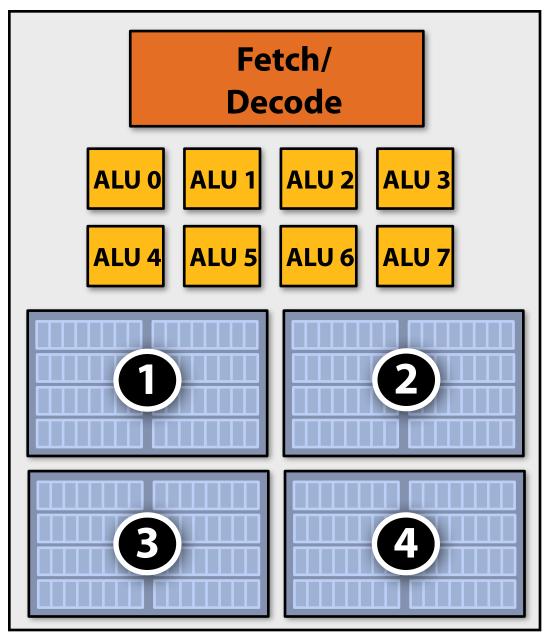

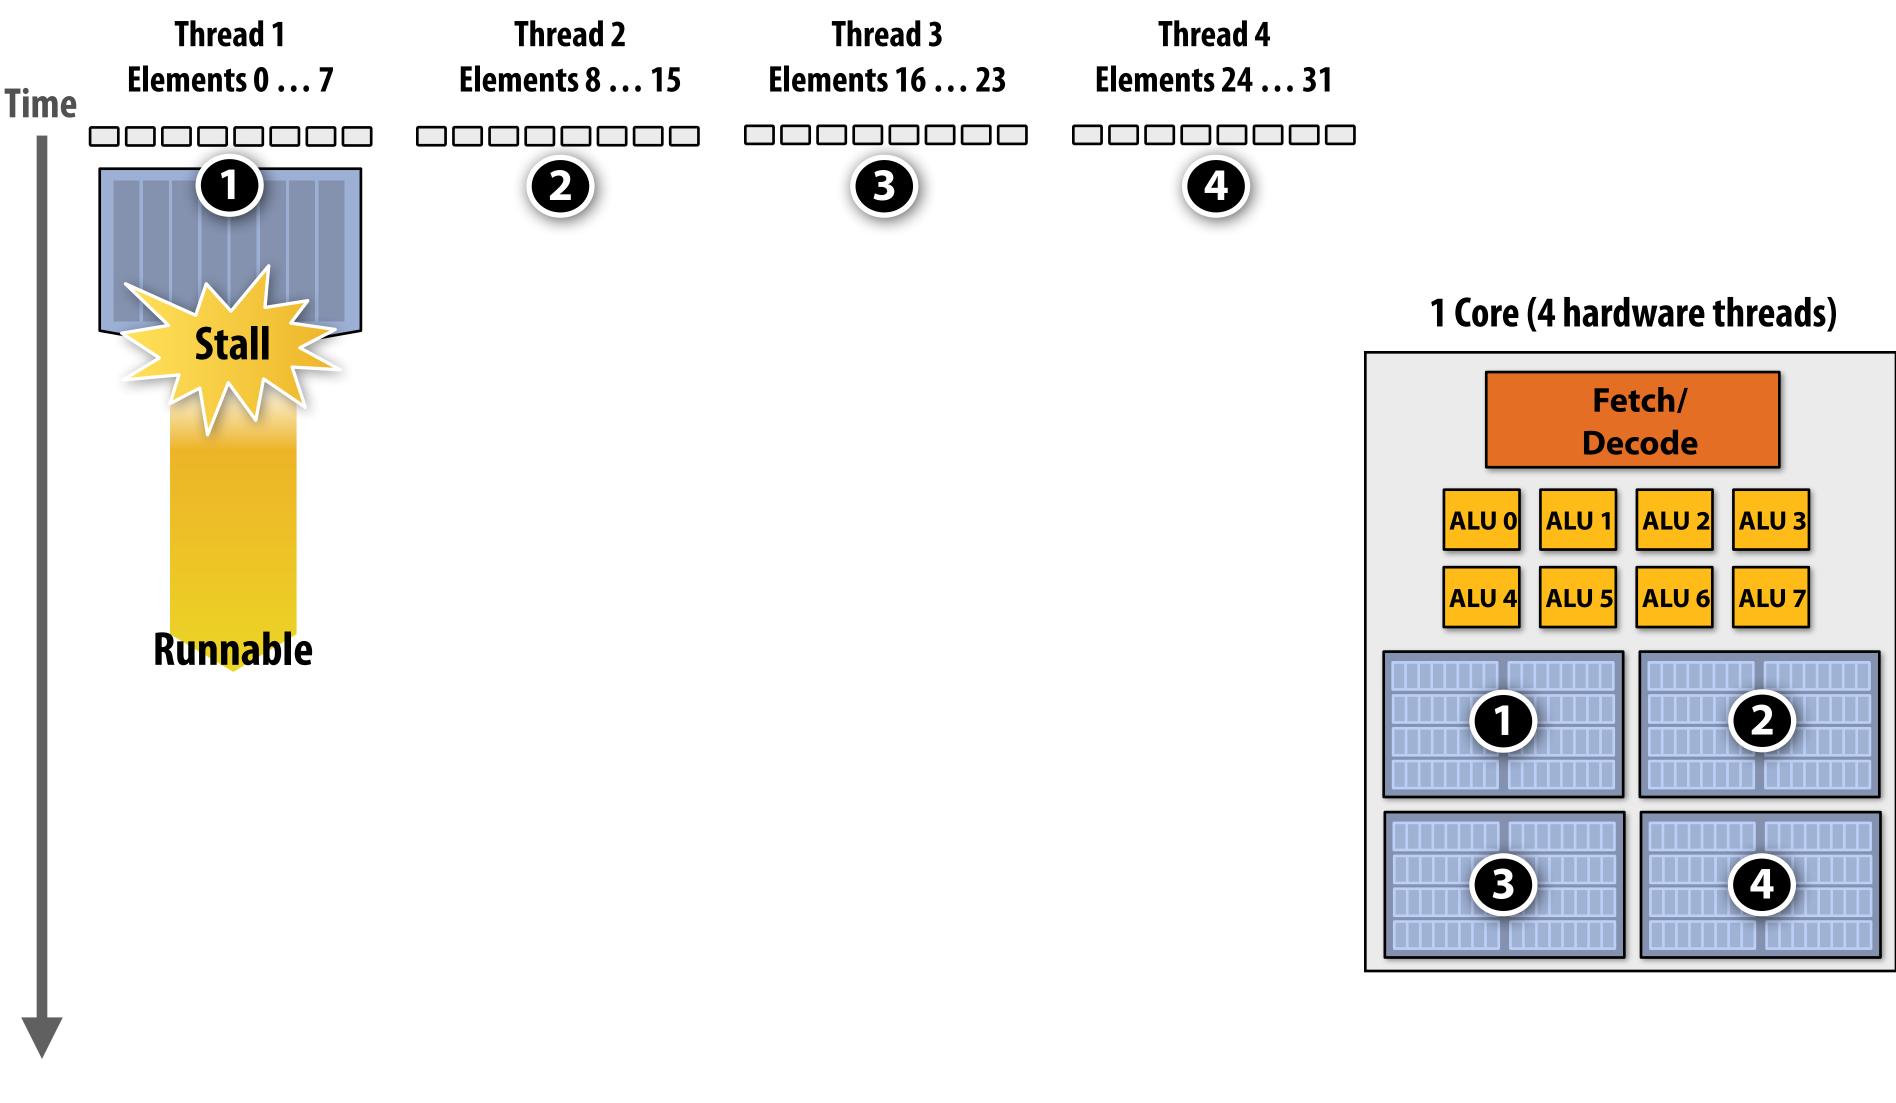

1 Core (1 thread)

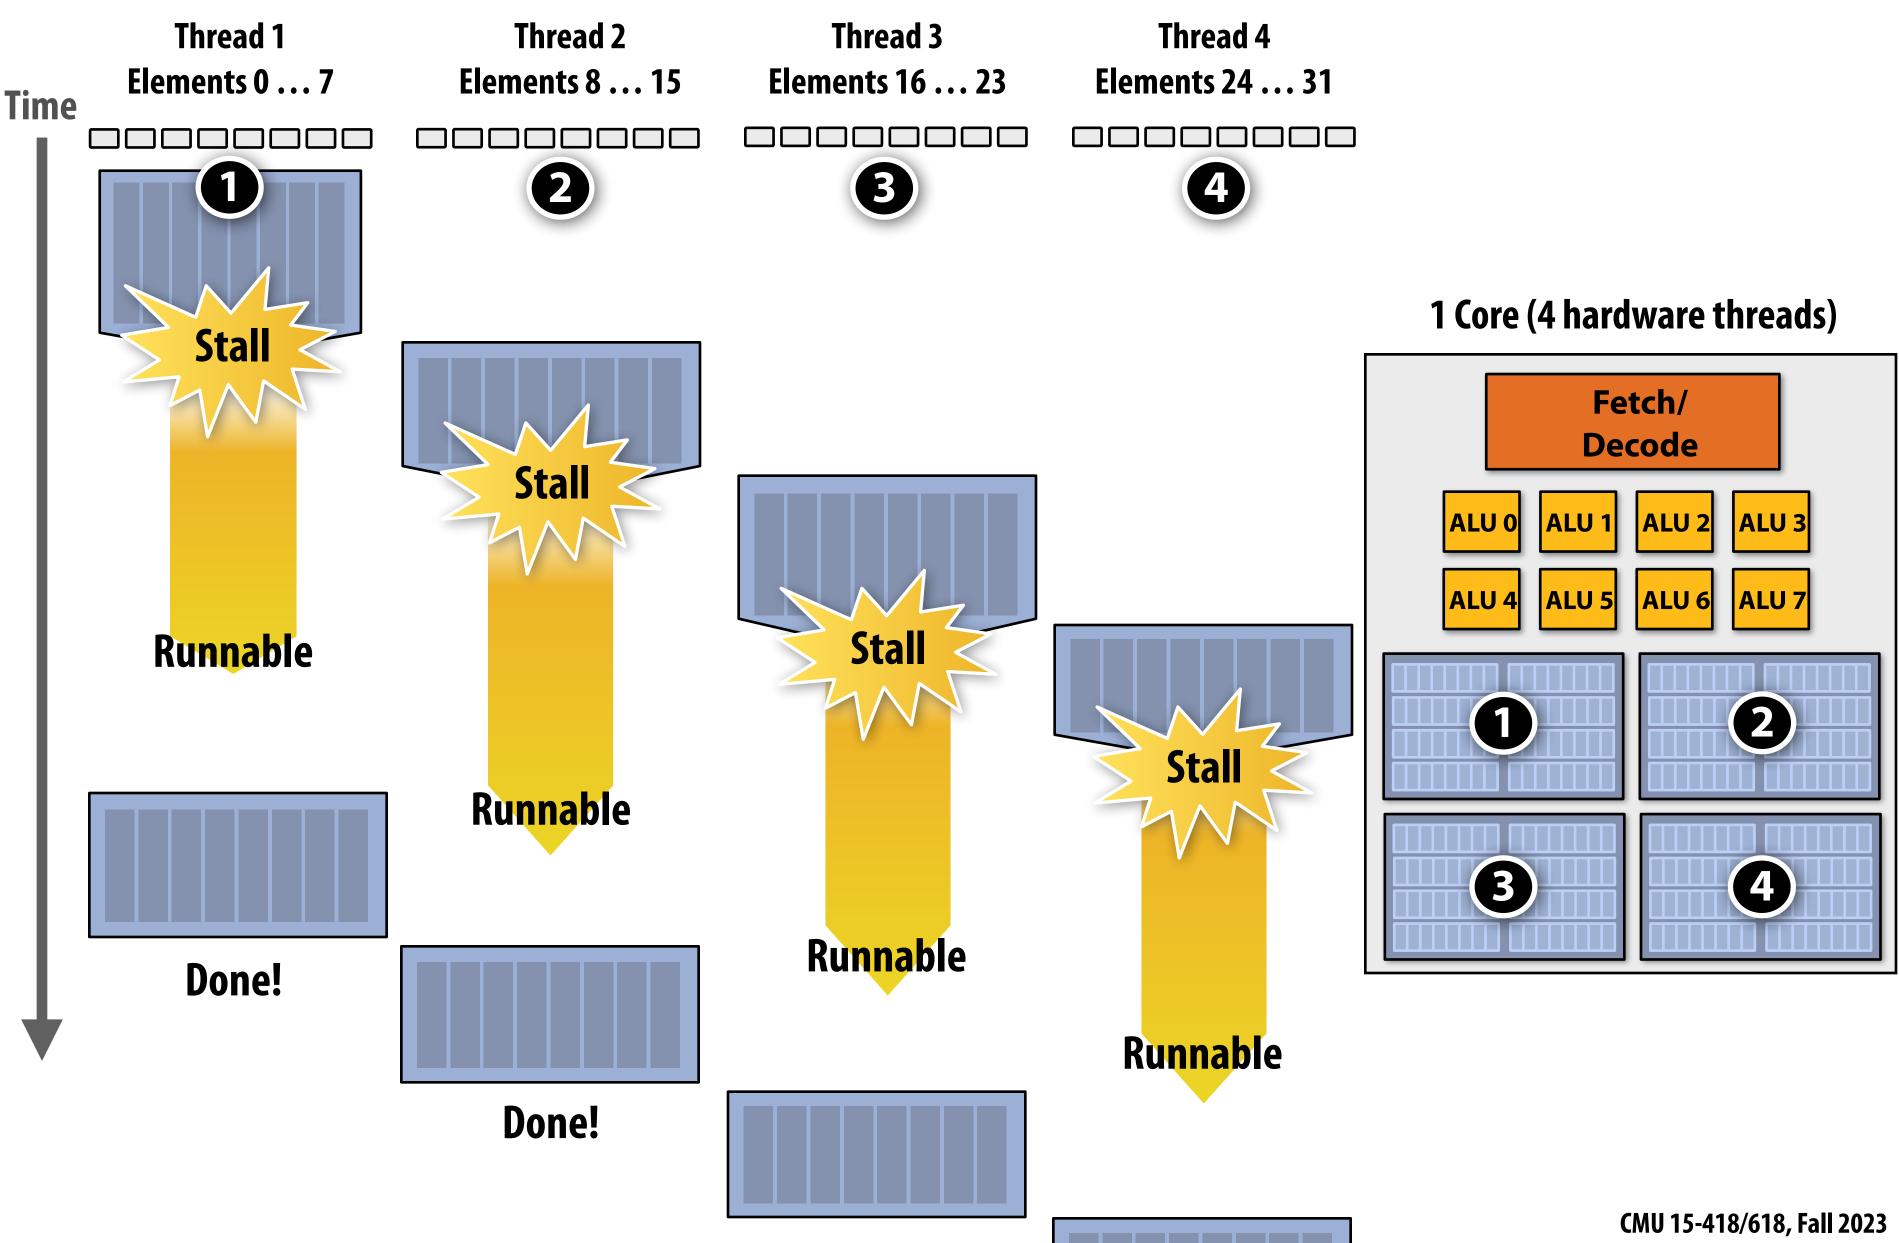

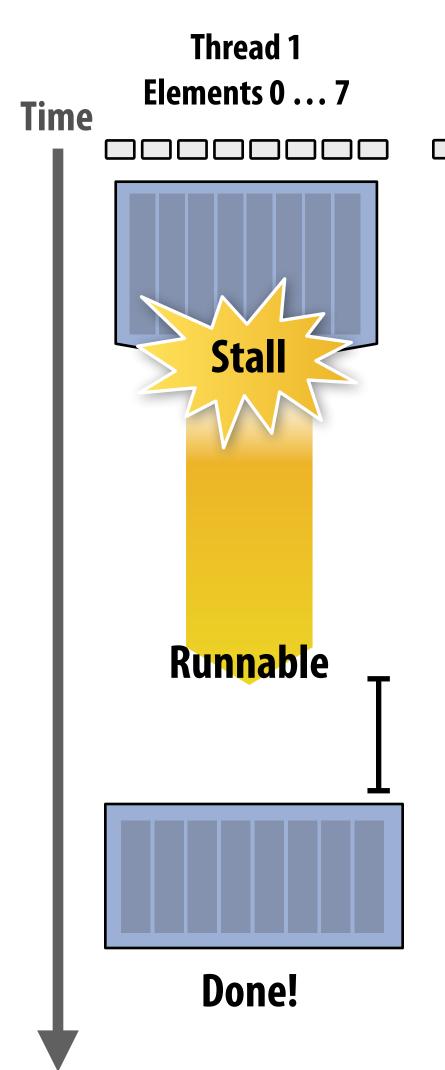

1 Core (4 hardware threads)

Throughput computing trade-off

 Thread 2
 Thread 3
 Thread 4

 Elements 8 ... 15
 Elements 16 ... 23
 Elements 24 ... 31

 Image: Second system
 Image: Second system
 Image: Second system

Key idea of throughput-oriented systems: Potentially increase time to complete work by any one any one thread, in order to increase overall system throughput when running multiple threads.

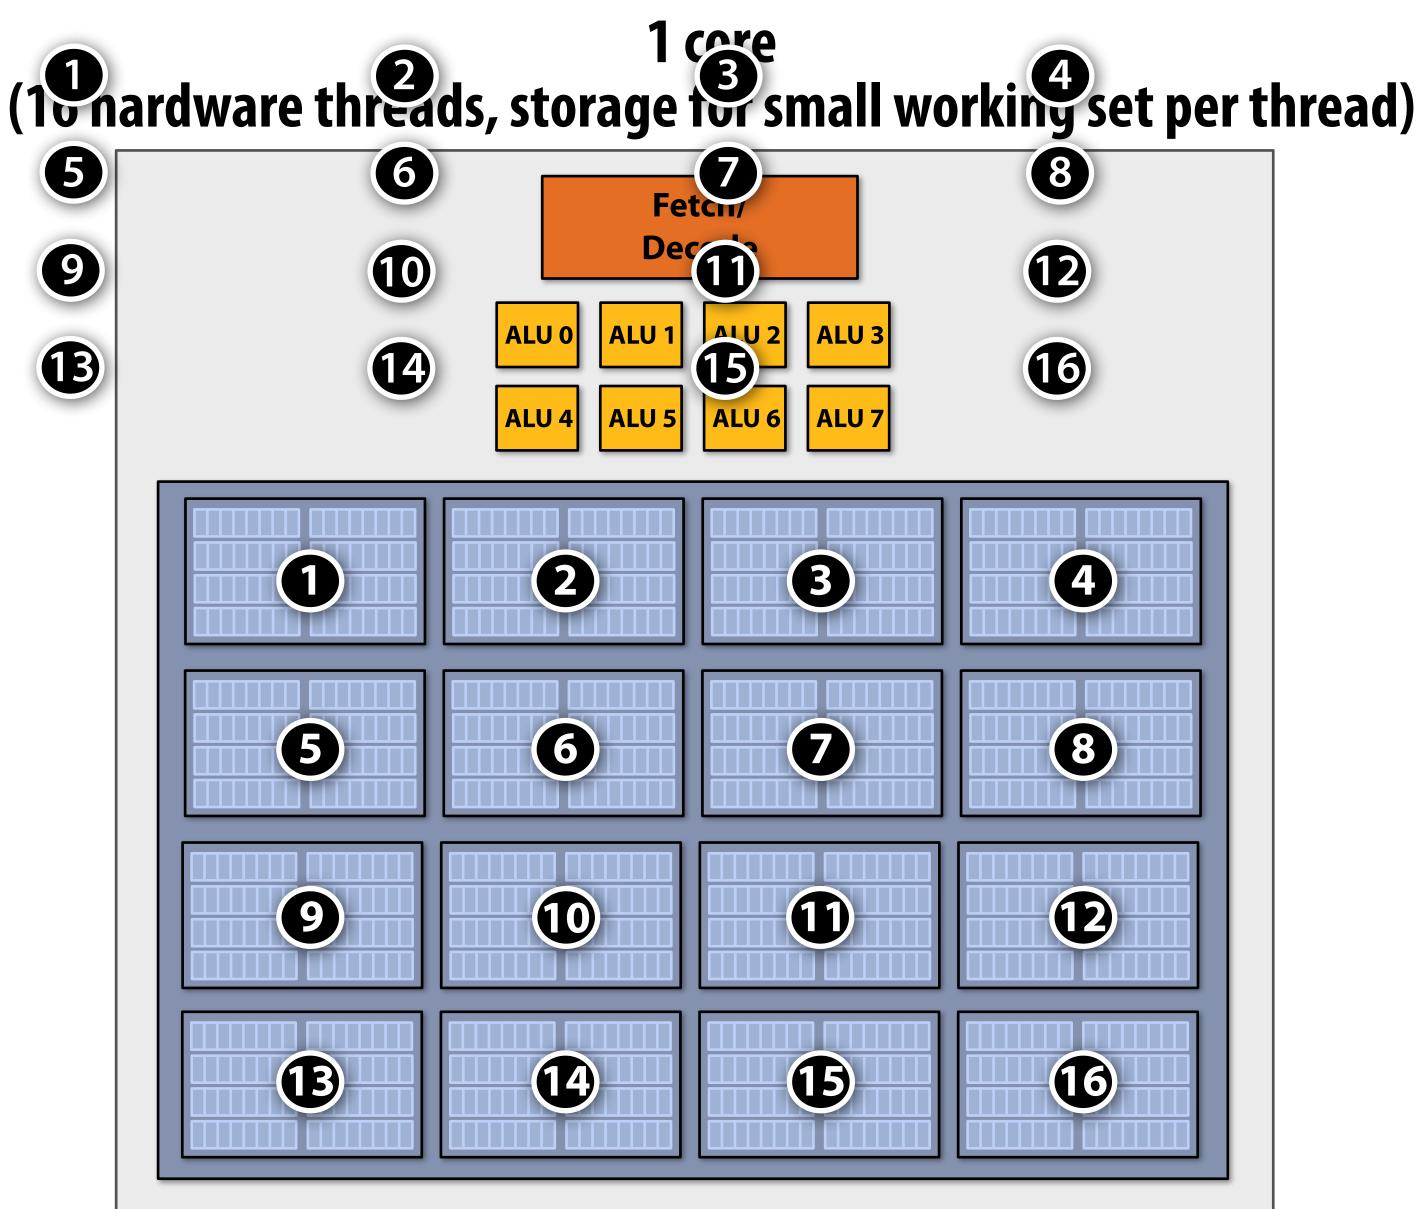

During this time, this thread is runnable, but it is not being executed by the processor. (The core is running some other thread.)

Storing execution contexts

Consider on ship storage of execution contexts a finite resource.

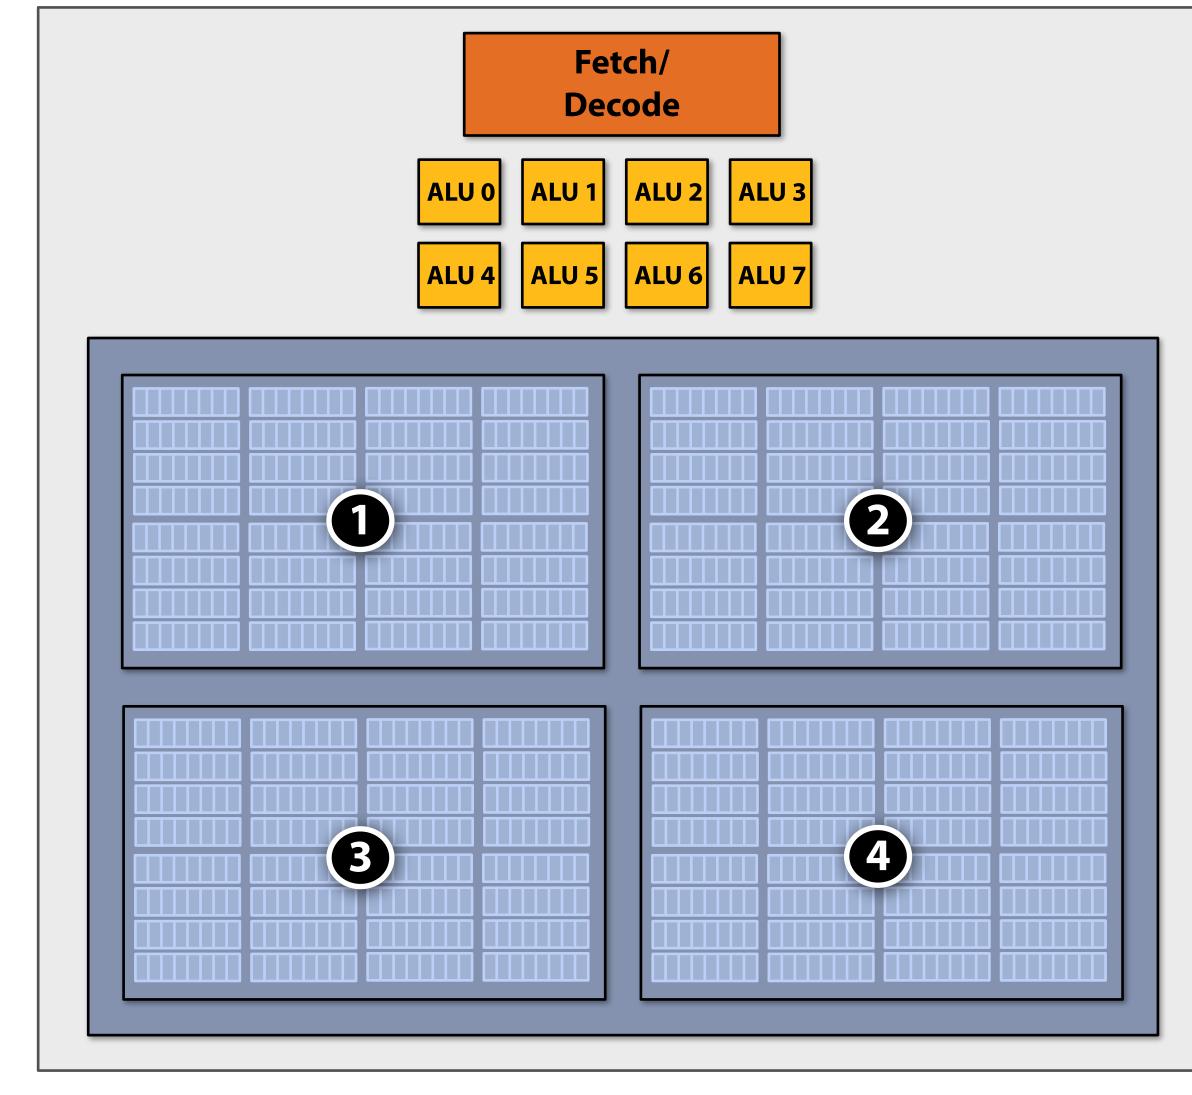

Many small contexts (high latency hiding ability)

16	

Four large contexts (low latency hiding ability)

1 core (4 Pardware threads, storage for larger working set per thread)

Hardware-supported multi-threading

Core manages execution contexts for multiple threads

- Runs instructions from runnable threads (processor makes decision about which thread to run each clock, not the operating system)
- Core still has the same number of ALU resources: multi-threading only helps use them more efficiently in the face of high-latency operations like memory access

Interleaved multi-threading (a.k.a. temporal multi-threading)

- What I described on the previous slides: each clock, the core chooses a thread, and runs an instruction from the thread on the ALUs

Simultaneous multi-threading (SMT)

- Each clock, core chooses instructions from multiple threads to run on ALUs
- **Extension of superscalar CPU design**
- Example: Intel Hyper-threading (2 threads per core)

Multi-threading summary

Benefit: use a core's ALU resources more efficiently

- Hide memory latency
- Fill multiple functional units of superscalar architecture (when one thread has insufficient ILP)

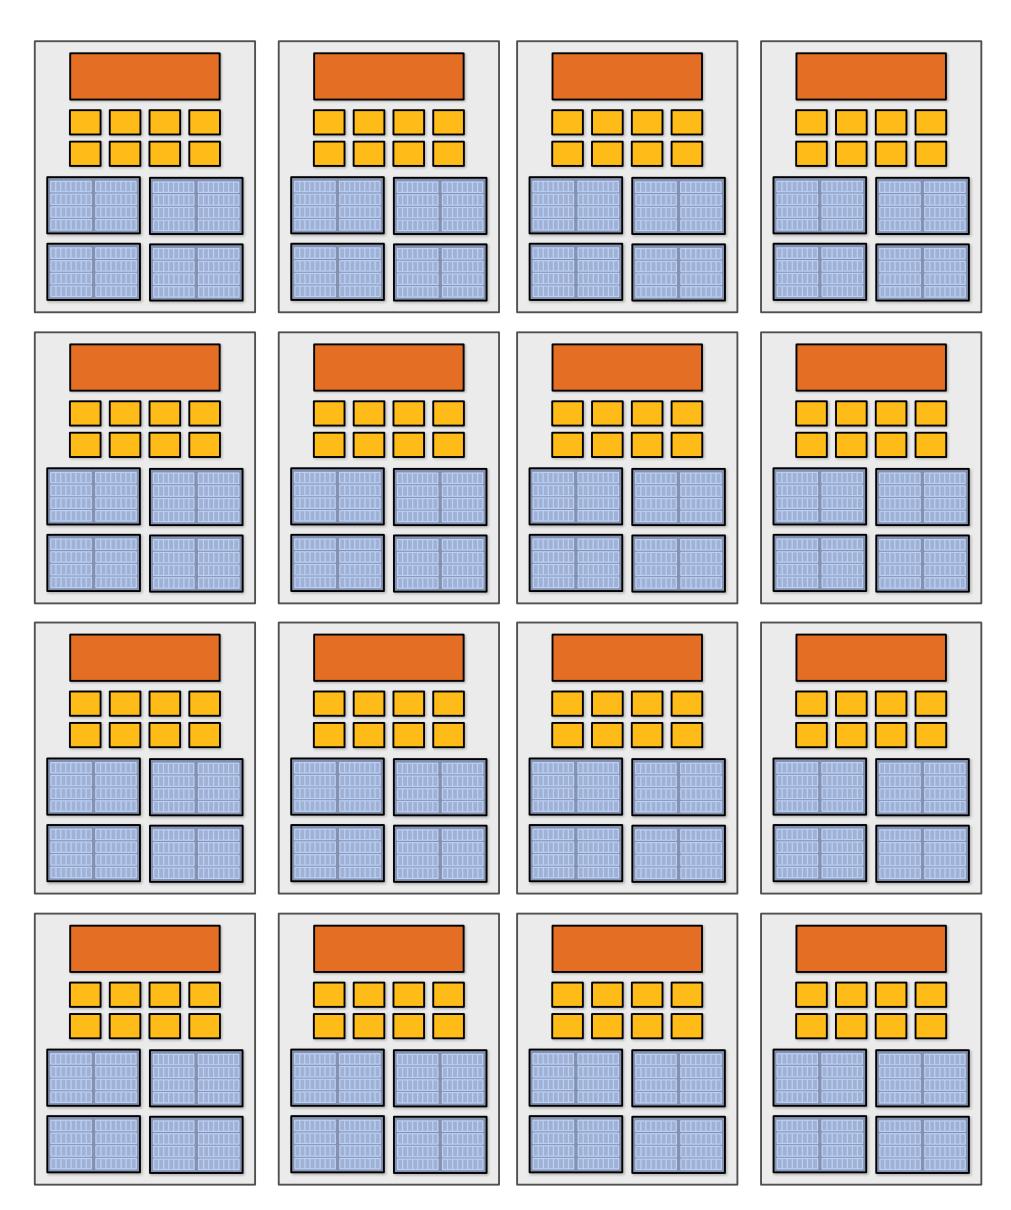

Costs

- **Requires additional storage for thread contexts**
- Increases run time of any single thread (often not a problem, we usually care about throughput in parallel apps)
- **Requires additional independent work in a program (more independent work** than ALUs!)
- **Relies heavily on memory bandwidth**
 - More threads \rightarrow larger working set \rightarrow less cache space per thread
 - May go to memory more often, but can hide the latency

Our fictitious multi-core chip

16 cores

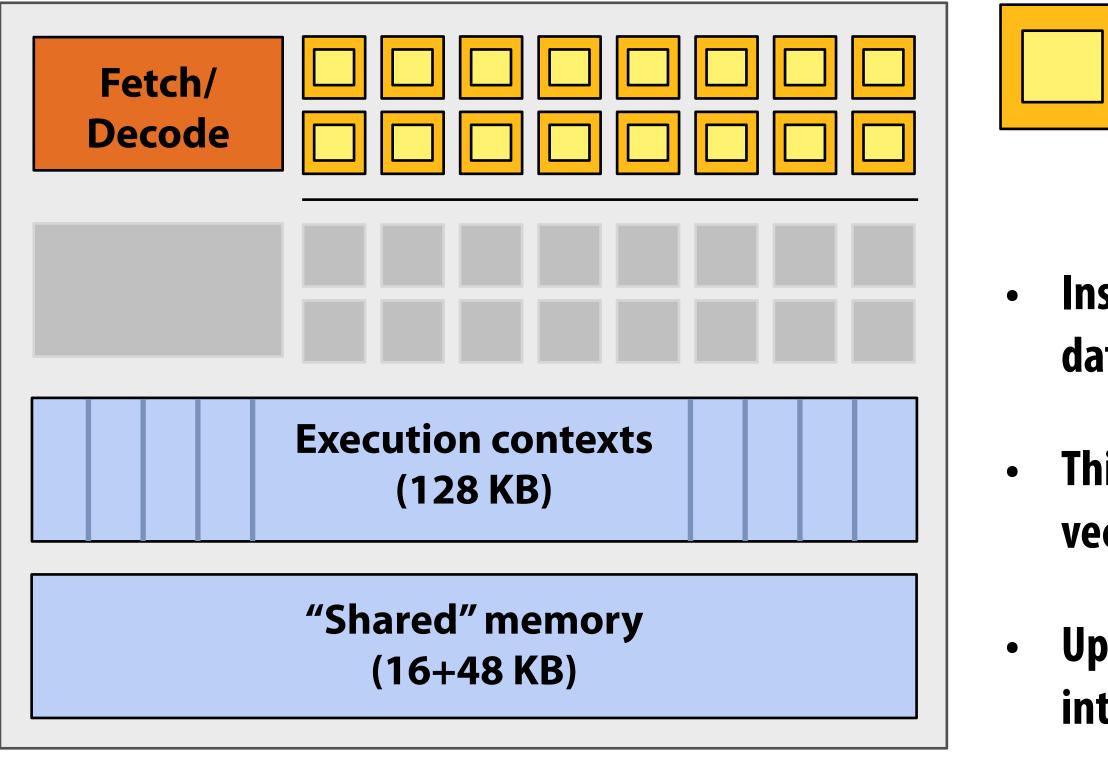

- 8 SIMD ALUs per core (128 total)
- 4 threads per core
- 16 simultaneous instruction streams
- 64 total concurrent instruction streams
- 512 independent pieces of work are needed to run chip with maximal latency hiding ability

CMU 15-418/618, Fall 2023

GPUs: Extreme throughput-oriented processors

NVIDIA GTX 480 core

Source: Fermi Compute Architecture Whitepaper CUDA Programming Guide 3.1, Appendix G

= SIMD function unit, control shared across 16 units (1 MUL-ADD per clock)

Instructions operate on 32 pieces of data at a time (called "warps").

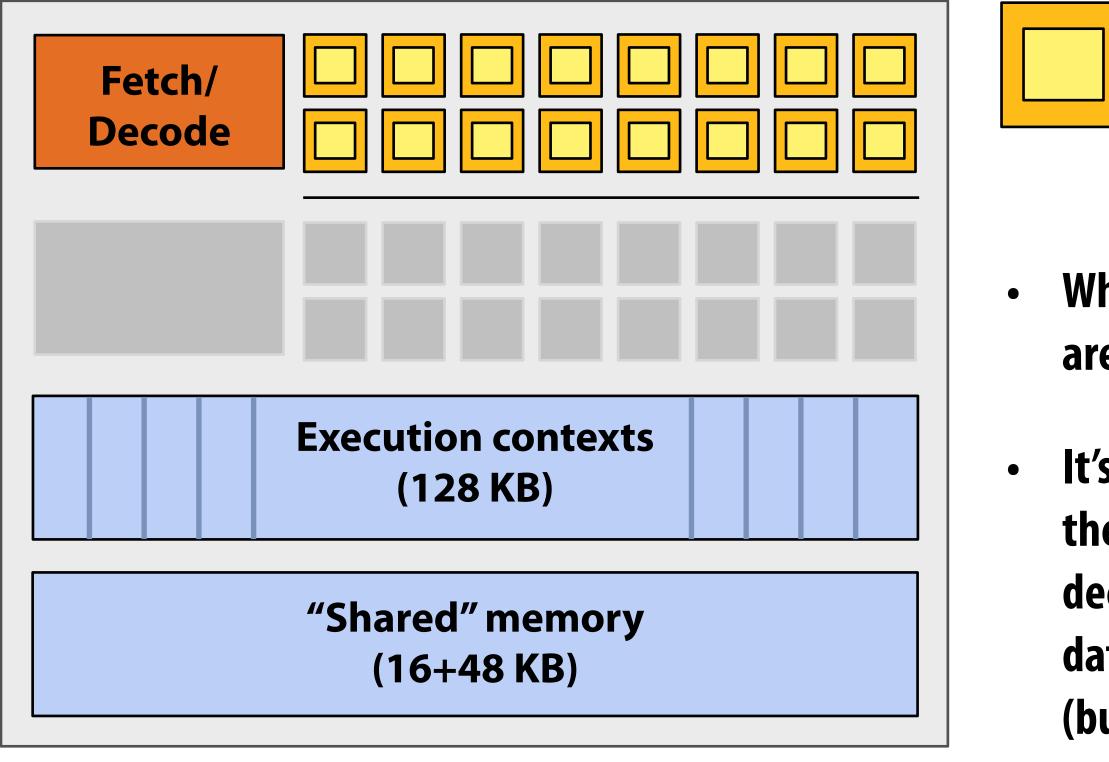

Think: warp = thread issuing 32-wide vector instructions

Up to 48 warps are simultaneously interleaved

Over 1500 elements can be processed concurrently by a core

NVIDIA GTX 480: more detail (just for the curious)

NVIDIA GTX 480 core

Source: Fermi Compute Architecture Whitepaper CUDA Programming Guide 3.1, Appendix G

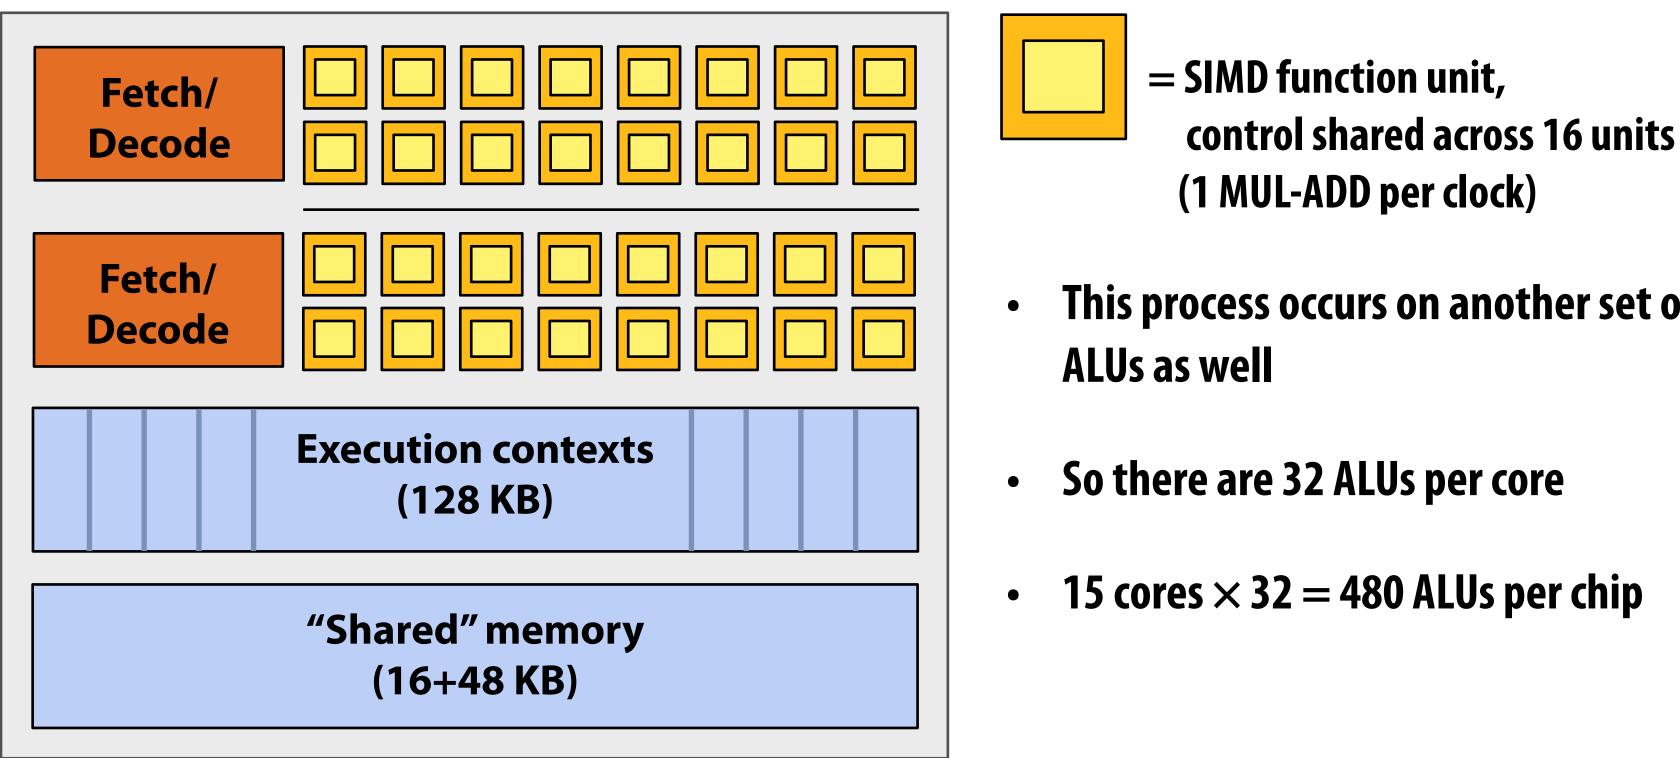

= SIMD function unit, control shared across 16 units (1 MUL-ADD per clock)

Why is a warp 32 elements and there are only 16 SIMD ALUs?

It's a bit complicated: ALUs run at twice the clock rate of rest of chip. So each decoded instruction runs on 32 pieces of data on the 16 ALUs over two ALU clocks. (but to the programmer, it behaves like a 32-wide SIMD operation)

NVIDIA GTX 480: more detail (just for the curious)

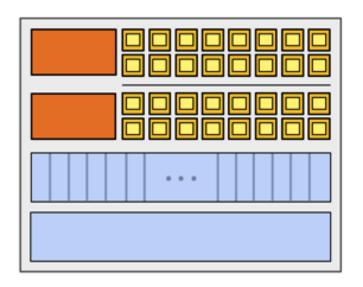

NVIDIA GTX 480 core

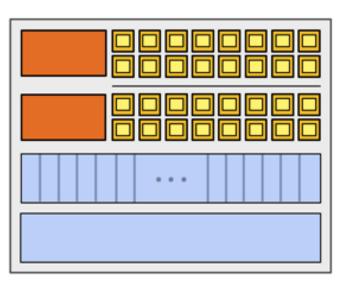

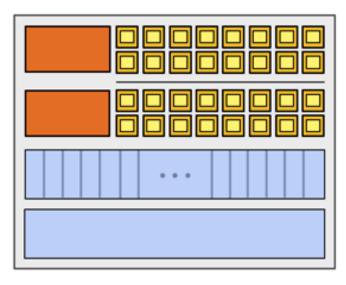

Source: Fermi Compute Architecture Whitepaper CUDA Programming Guide 3.1, Appendix G

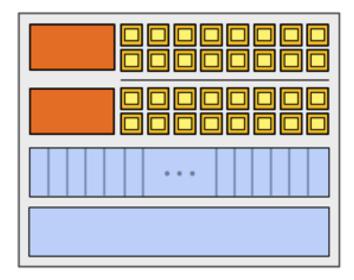

This process occurs on another set of 16

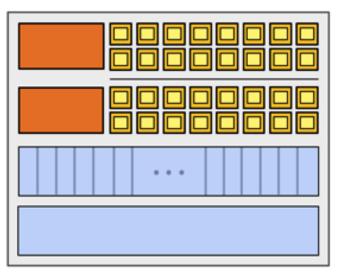

NVIDIA GTX 480

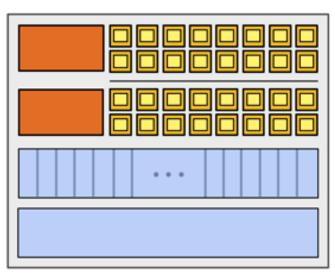

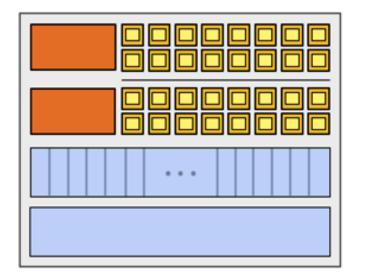

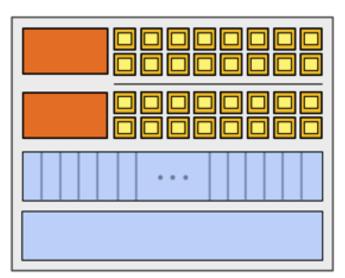

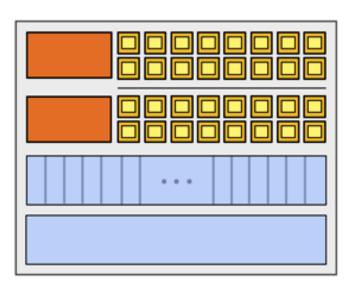

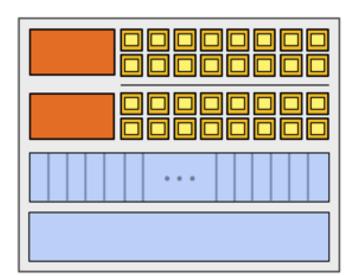

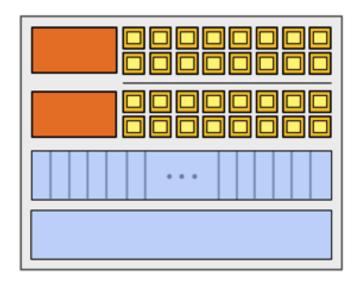

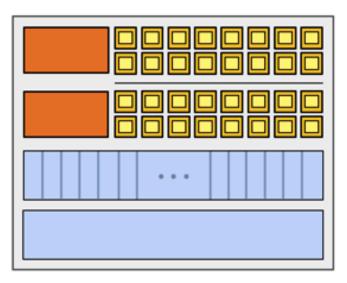

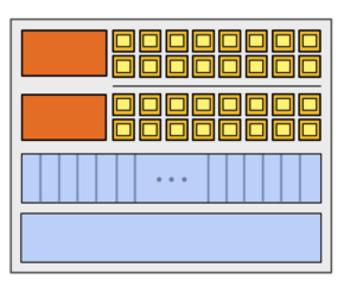

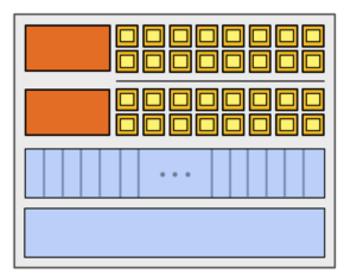

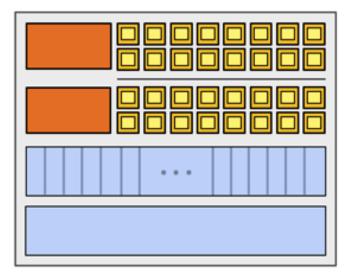

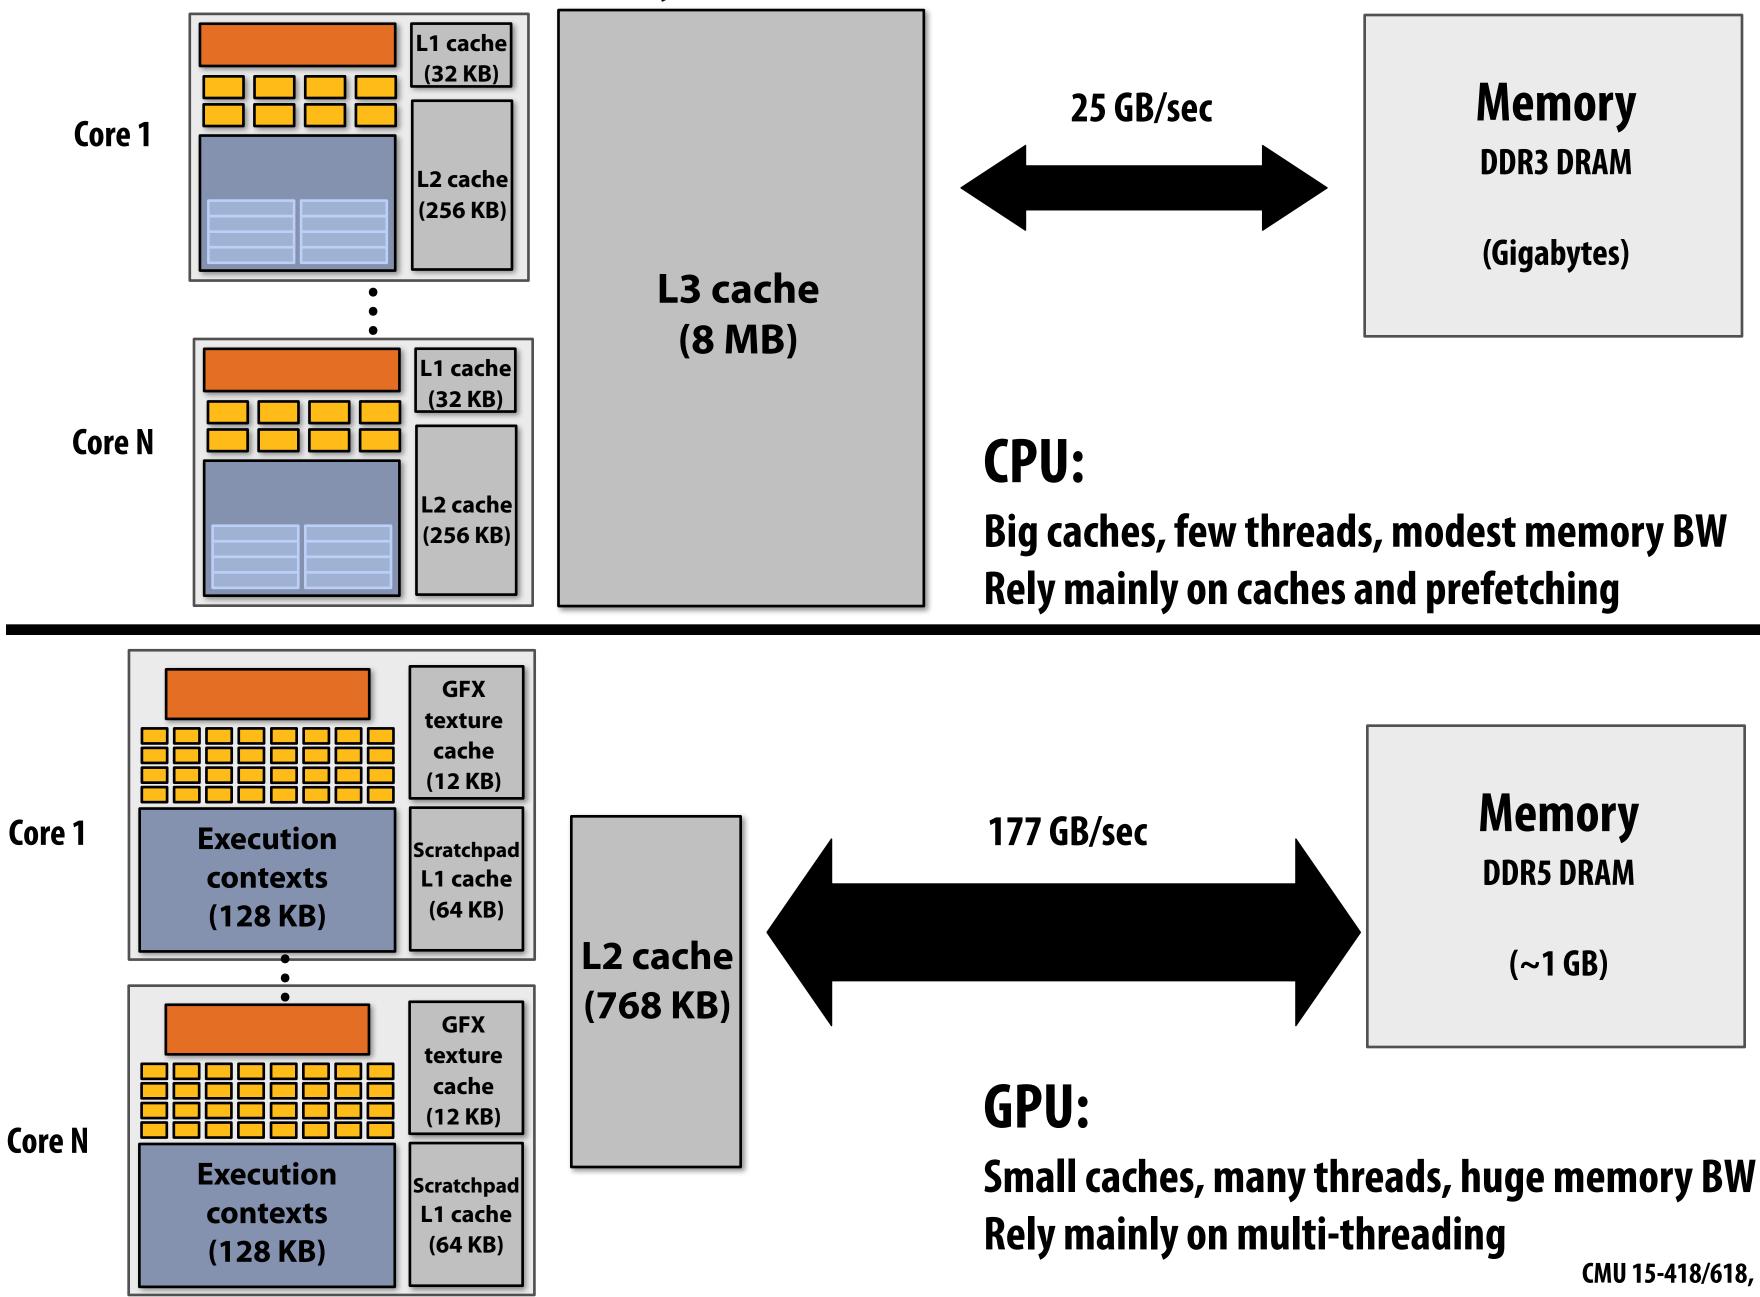

Recall, there are 15 cores on the GTX 480: That's 23,000 pieces of data being processed concurrently!

CPU vs. GPU memory hierarchies

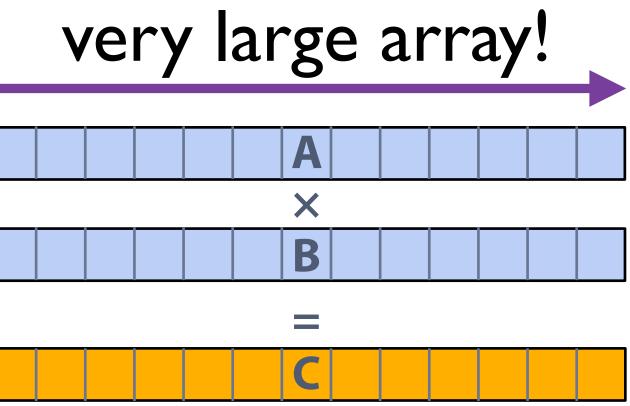

Thought experiment

Task: element-wise multiplication of two vectors A and B **Assume vectors contain millions of elements**

- Load input A[i]
- Load input B[i]
- Compute $A[i] \times B[i]$
- Store result into C[i]

Three memory operations (12 bytes) for every MUL NVIDIA GTX 480 GPU can do 480 MULs per clock (@ 1.2 GHz) Need ~6.4 TB/sec of bandwidth to keep functional units busy (only have 177 GB/sec) ~ 3% efficiency... but 7x faster than quad-core CPU! (2.6 GHz Core i7 Gen 4 quad-core CPU connected to 25 GB/sec memory bus will exhibit similar efficiency on this computation)

Bandwidth limited!

If processors request data at too high a rate, the memory system cannot keep up.

No amount of latency hiding helps this.

Overcoming bandwidth limits are a common challenge for application developers on throughput-optimized systems.

Bandwidth is a critical resource

Performant parallel programs will:

- **Organize computation to fetch data from <u>memory</u> less often**
 - **Reuse data previously loaded by the same thread** (traditional intra-thread temporal locality optimizations)
 - Share data across threads (inter-thread cooperation)
- Request data less often (instead, do more arithmetic: it's "free")
 - Useful term: "arithmetic intensity" ratio of math operations to data access operations in an instruction stream
 - **Main point: programs must have high arithmetic intensity to utilize** modern processors efficiently

Summary

- Three major ideas that all modern processors employ to varying degrees
 - Employ multiple processing cores
 - Simpler cores (embrace thread-level parallelism over instruction-level parallelism)
 - Amortize instruction stream processing over many ALUs (SIMD)
 - Increase compute capability with little extra cost
 - Use multi-threading to make more efficient use of processing resources (hide latencies, fill all available resources)
- Due to high arithmetic capability on modern chips, many parallel applications (on both CPUs and GPUs) are **bandwidth bound**
- **GPU architectures use the same throughput computing ideas as CPUs:** but GPUs push these concepts to extreme scales

For the rest of this class, know these terms

- Multi-core processor
- SIMD execution
- Coherent control flow
- Hardware multi-threading
 - Interleaved multi-threading
 - Simultaneous multi-threading
- Memory latency
- Memory bandwidth
- Bandwidth bound application
- Arithmetic intensity

Another example: for review and to check your understanding (if you understand the following sequence you understand this lecture)

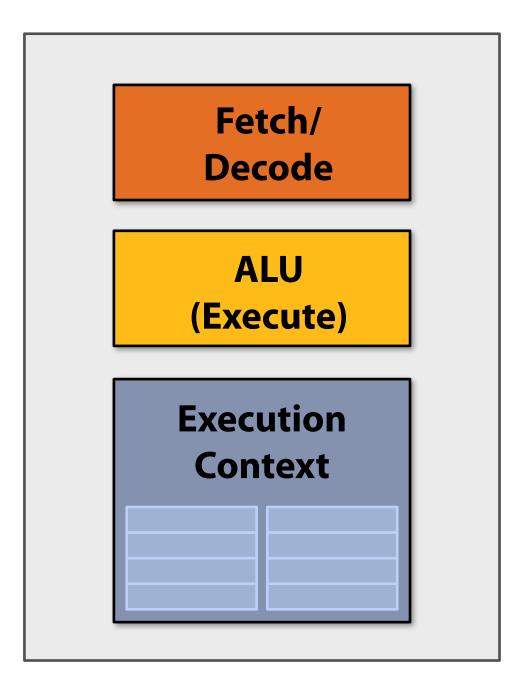

Running code on a simple processor

My very simple program: compute sin(x) using Taylor expansion

```
void sinx(int N, int terms, float* x, float* result)
   for (int i=0; i<N; i++)</pre>
   {
      float value = x[i];
      float numer = x[i] * x[i] * x[i];
      int denom = 6; // 3!
      int sign = -1;
      for (int j=1; j<=terms; j++)</pre>
      {
         value += sign * numer / denom;
         numer *= x[i] * x[i];
         denom *= (2*j+2) * (2*j+3);
         sign *= -1;
      }
      result[i] = value;
```

My very simple processor: completes one instruction per clock

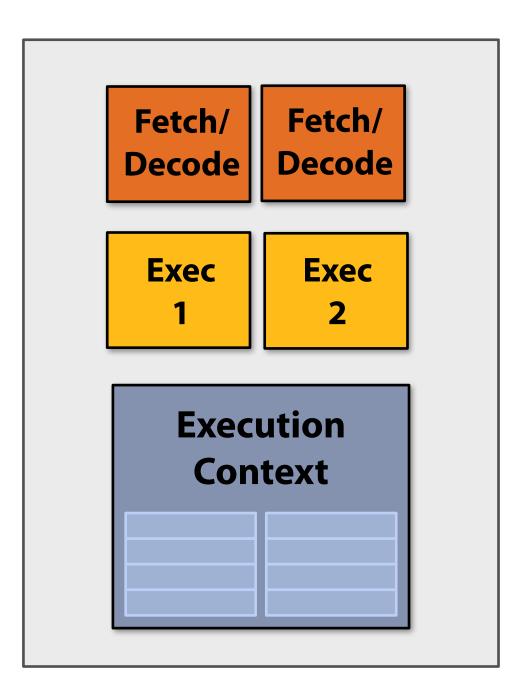

Review: superscalar execution

Unmodified program

```
void sinx(int N, int terms, float* x, float* result)
   for (int i=0; i<N; i++)</pre>
   {
      float value = x[i];
      float numer = x[i] * x[i] * x[i];
      int denom = 6; // 3!
      int sign = -1;
      for (int j=1; j<=terms; j++)</pre>
      {
          value += sign * numer / denom;
          numer *= x[i] * x[i];
          denom *= (2*j+2) * (2*j+3),
          sign *= -1;
                                           Independent operations in
      }
                                               instruction stream
      result[i] = value;
                                       (They are detected by the processor
                                       at run-time and <u>may</u> be executed in
                                       parallel on execution units 1 and 2)
```

My single core, superscalar processor: executes up to <u>two instructions</u> per clock from <u>a single instruction stream</u>.

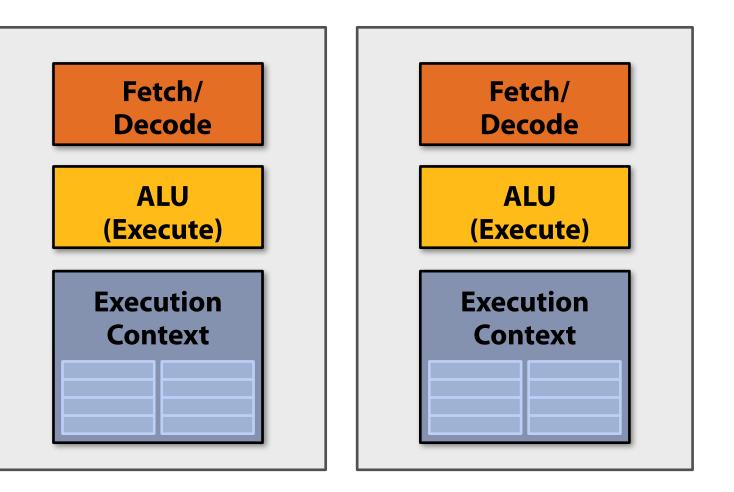

Review: multi-core execution (two cores)

Modify program to create two threads of control (two instruction streams)

```
typedef struct {
   int N;
   int terms;
  float* x;
  float* result;
} my_args;
void parallel_sinx(int N, int terms, float* x, float* result)
{
    pthread_t thread_id;
    my args args;
    args.N = N/2;
    args.terms = terms;
    args.x = x;
    args.result = result;
    pthread_create(&thread_id, NULL, my_thread_start, &args); // launch thread
    sinx(N - args.N, terms, x + args.N, result + args.N); // do work
    pthread_join(thread_id, NULL);
void my_thread_start(void* thread_arg)
   my_args* thread_args = (my_args*)thread_arg;
   sinx(args->N, args->terms, args->x, args->result); // do work
```

My dual-core processor: executes one instruction per clock from an instruction stream on <u>each</u> core.

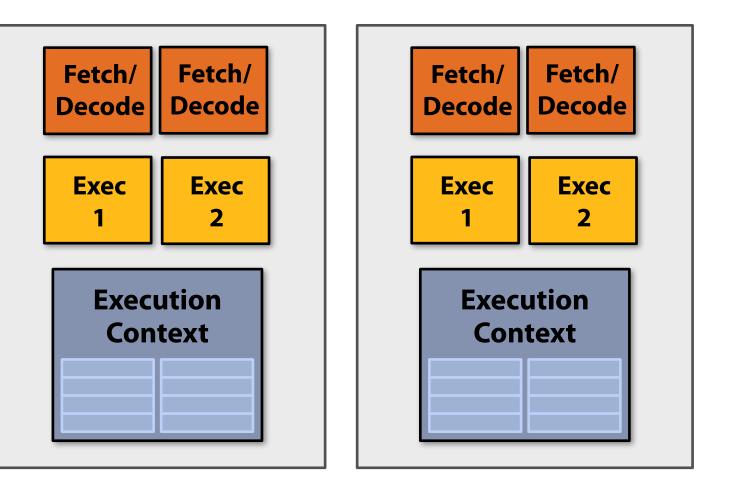

Review: multi-core + superscalar execution

Modify program to create two threads of control (two instruction streams)

```
typedef struct {
   int N;
   int terms;
  float* x;
  float* result;
} my_args;
void parallel_sinx(int N, int terms, float* x, float* result)
{
    pthread_t thread_id;
    my args args;
    args.N = N/2;
    args.terms = terms;
    args.x = x;
    args.result = result;
    pthread_create(&thread_id, NULL, my_thread_start, &args); // launch thread
    sinx(N - args.N, terms, x + args.N, result + args.N); // do work
    pthread_join(thread_id, NULL);
void my_thread_start(void* thread_arg)
   my_args* thread_args = (my_args*)thread_arg;
   sinx(args->N, args->terms, args->x, args->result); // do work
```

My <u>superscalar</u> dual-core processor: executes up to two instructions per clock from an instruction stream on each core.

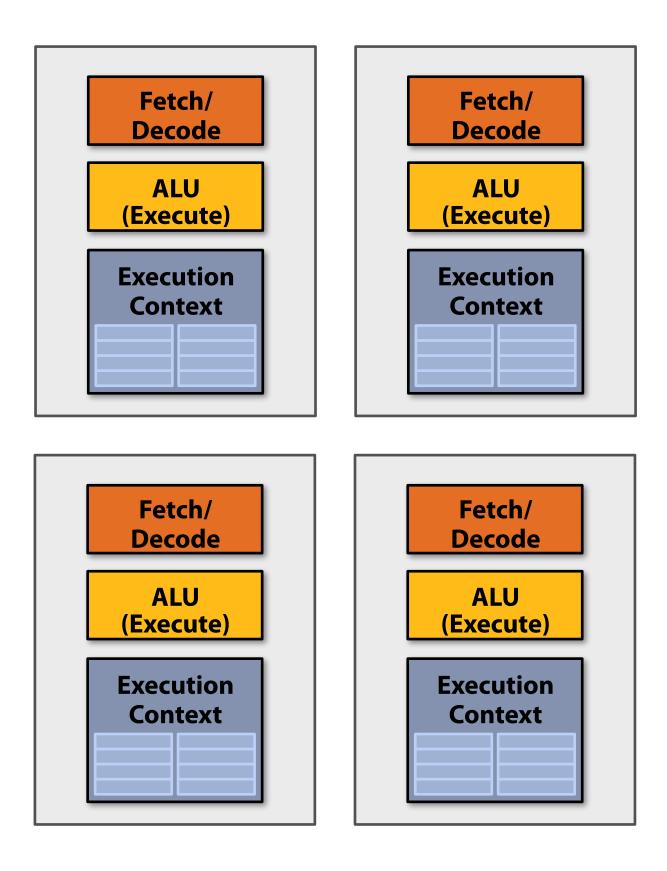

Review: multi-core (four cores)

Modify program to create many threads of control: recall our fictitious language

```
void sinx(int N, int terms, float* x, float* result)
{
   // declare independent loop iterations
   forall (int i from 0 to N-1)
   {
      float value = x[i];
      float numer = x[i] * x[i] * x[i];
      int denom = 6; // 3!
      int sign = -1;
      for (int j=1; j<=terms; j++)</pre>
      {
         value += sign * numer / denom
         numer *= x[i] * x[i];
         denom *= (2*j+2) * (2*j+3);
         sign *= -1;
      result[i] = value;
```

My quad-core processor: executes one instruction per clock from an instruction stream on <u>each</u> core.

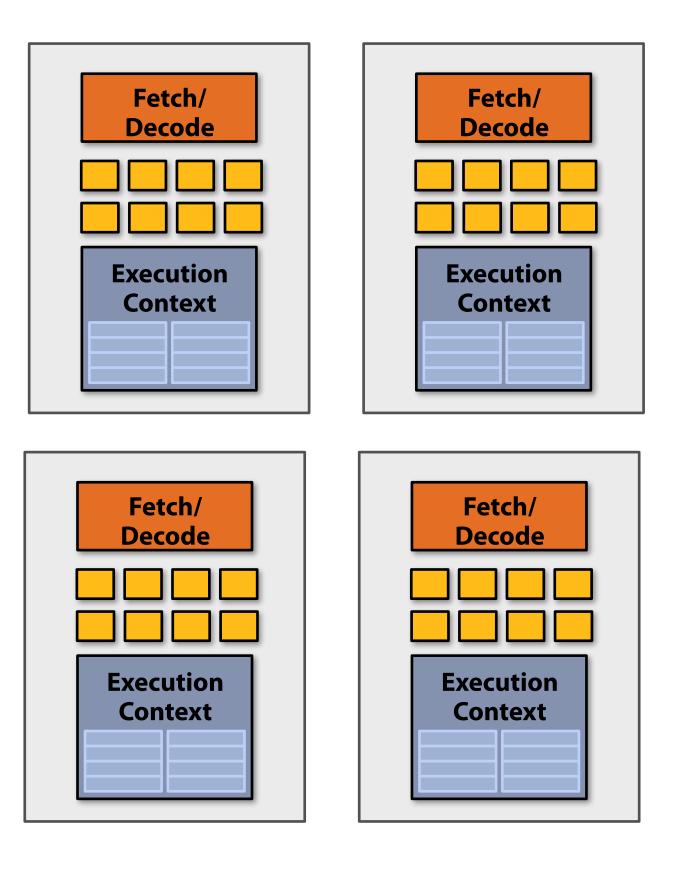

Review: four, 8-wide SIMD cores

Observation: program must execute many iterations of the <u>same</u> loop body. Optimization: share instruction stream across execution of multiple iterations (single instruction multiple data = SIMD)

```
void sinx(int N, int terms, float* x, float* result)
{
   // declare independent loop iterations
   forall (int i from 0 to N-1)
   {
      float value = x[i];
      float numer = x[i] * x[i] * x[i];
      int denom = 6; // 3!
      int sign = -1;
      for (int j=1; j<=terms; j++)</pre>
      {
         value += sign * numer / denom
         numer *= x[i] * x[i];
         denom *= (2*j+2) * (2*j+3);
         sign *= -1;
      result[i] = value;
```

My SIMD quad-core processor: executes one 8-wide SIMD instruction per clock from an instruction stream on <u>each</u> core.

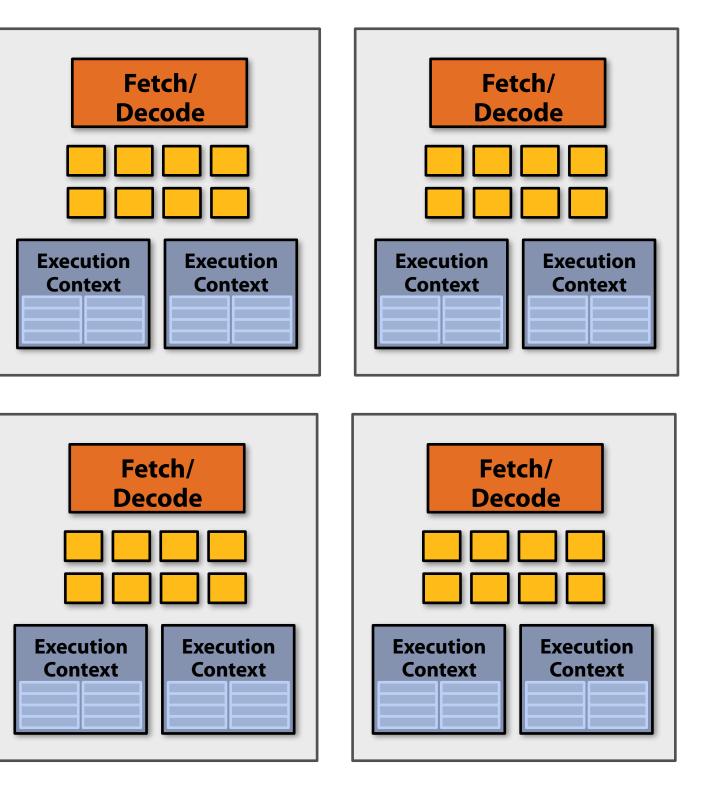

Review: four SIMD, multi-threaded cores

Observation: memory operations have very long latency Solution: hide latency of loading data for one iteration by executing arithmetic instructions from other iterations

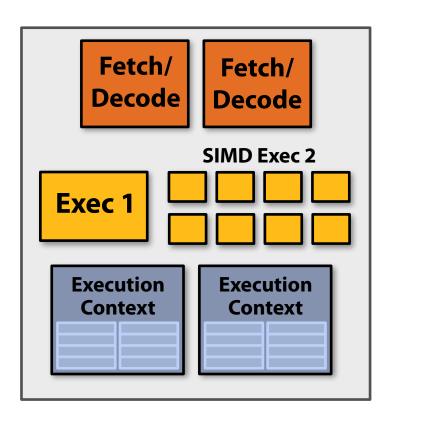

```
void sinx(int N, int terms, float* x, float* result)
{
   // declare independent loop iterations
   forall (int i from 0 to N-1)
   {
      float value { x[i];
                                           Memory load
      float numer = x[i] * x[i] * x[i];
      int denom = 6; // 3!
      int sign = -1;
      for (int j=1; j<=terms; j++)</pre>
      {
         value += sign * numer / denom
         numer *= x[i] * x[i];
         denom *= (2*j+2) * (2*j+3);
                                            Memory store
         sign *= -1;
      result[i] 
                 value;
```

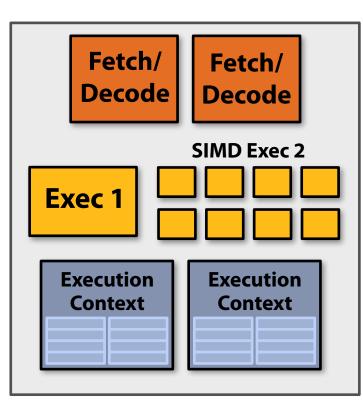

My <u>multi-threaded</u>, SIMD quad-core processor: executes one SIMD instruction per clock from one instruction stream on <u>each</u> core. But can switch to processing the other instruction stream when faced with a stall.

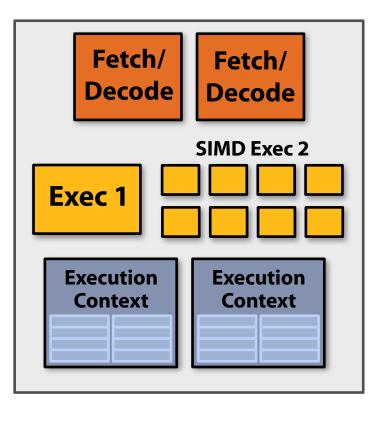

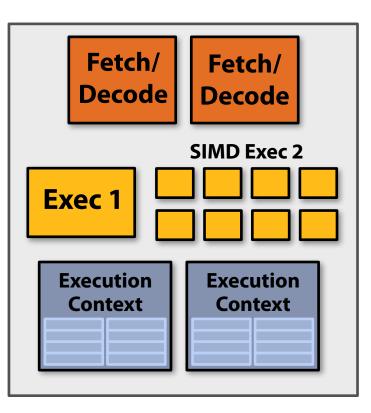

Summary: four superscalar, SIMD, multi-threaded cores

- My <u>multi-threaded</u>, superscalar, SIMD quad-core processor:
- executes up to two instructions per clock from one instruction stream on each core (in this example: one SIMD instruction + one scalar instruction).
- Processor can switch to execute the other instruction stream when faced with stall.

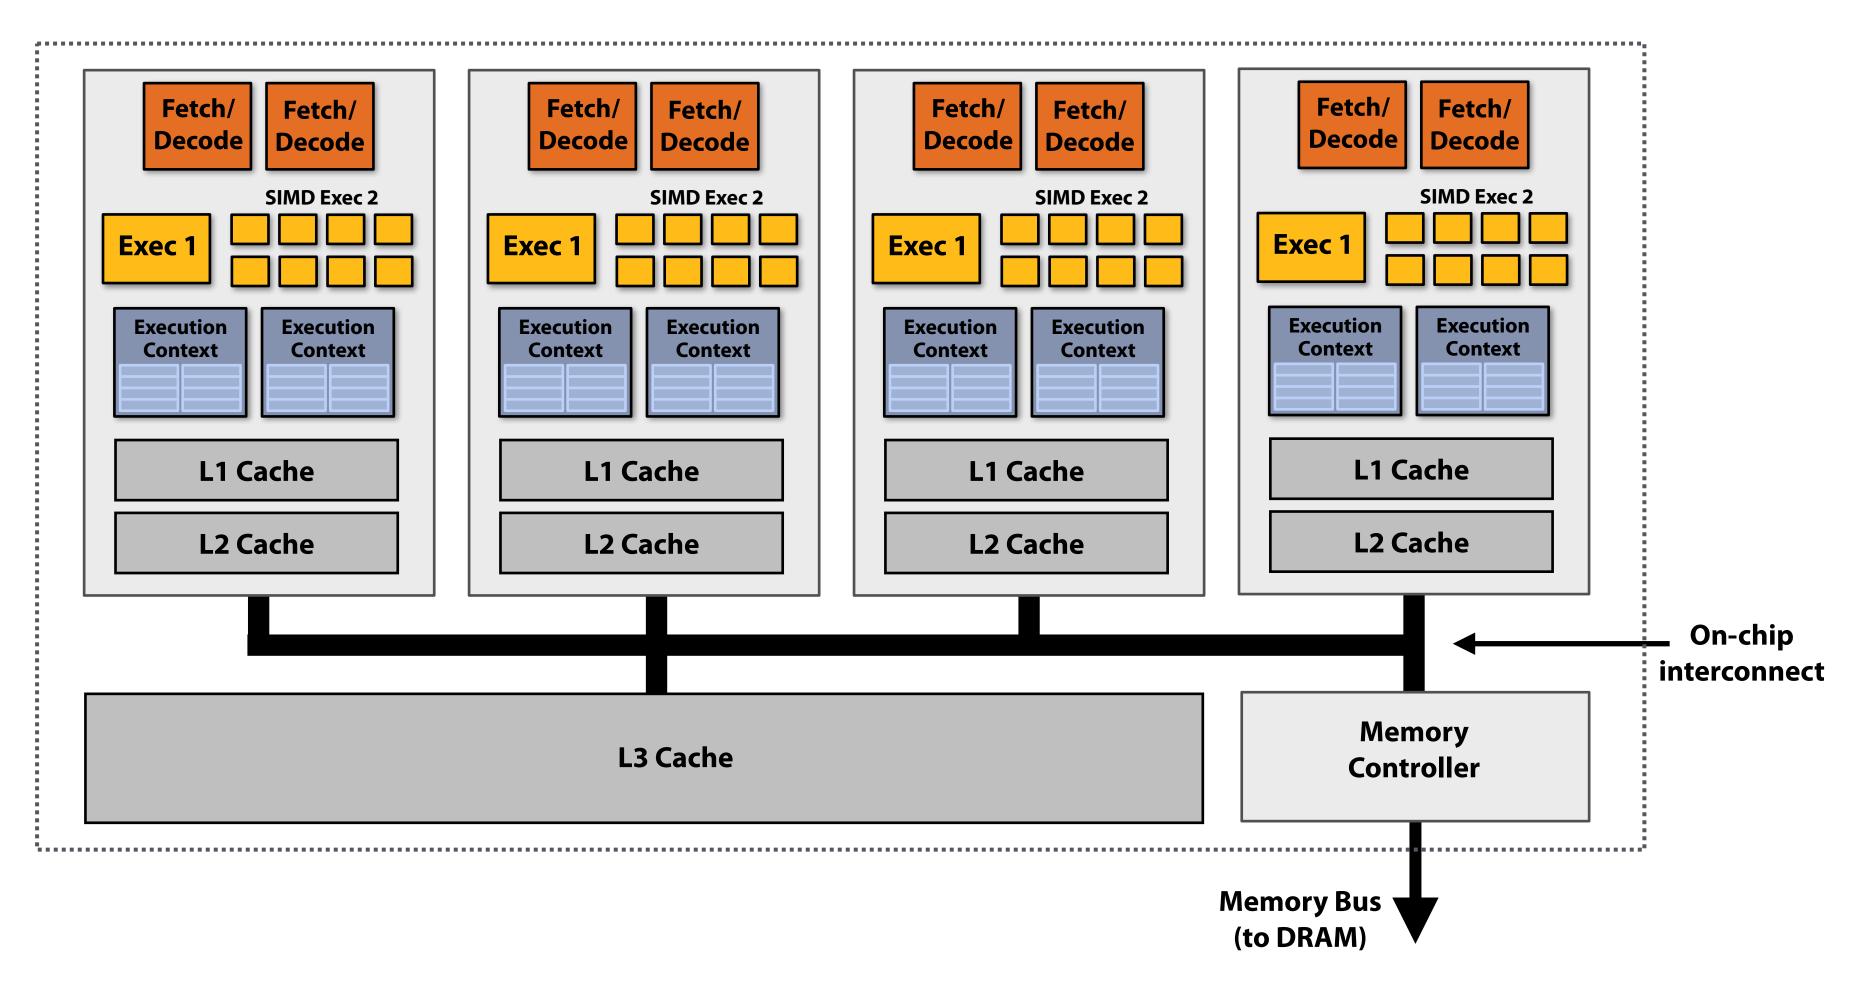

Connecting it all together

Our simple quad-core processor:

Four cores, two-way multi-threading per core (max eight threads active on chip at once), up to two instructions per clock per core (one of those instructions is 8-wide SIMD)

Thought experiment

- You write a C application that spawns <u>two</u> pthreads
- The application runs on the processor shown below
 - Two cores, two-execution contexts per core, up to instructions per clock, one instruction is an 8-wide SIMD instruction.
- Question: "who" is responsible for mapping your pthreads to the processor's thread execution contexts?

Answer: the operating system

- Question: If you were the OS, how would to assign the two threads to the four available execution contexts?
- **Another question: How would you** assign threads to execution contexts if your C program spawned <u>five</u> pthreads?
