

# **Dynamic Memory Allocation: Advanced Concepts**

18-213/18-613: Introduction to Computer Systems 15<sup>th</sup> Lecture, October 24, 2023

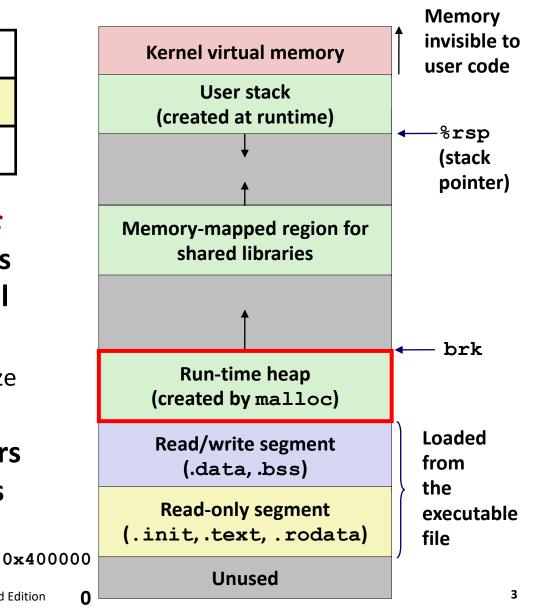

### **Review: Dynamic Memory Allocation**

Application

**Dynamic Memory Allocator** 

Heap

- Programmers use dynamic memory allocators (such as malloc) to acquire virtual memory (VM) at run time.
  - for data structures whose size is only known at runtime
- Dynamic memory allocators manage an area of process
   VM known as the *heap*.

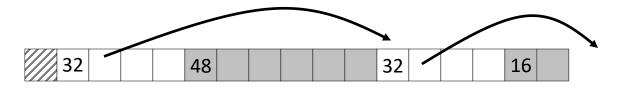

### **Review: Keeping Track of Free Blocks**

Method 1: Implicit list using length—links all blocks

Need to tag each block as allocated/free

Method 2: Explicit list among the free blocks using pointers

Need space for pointers

Method 3: Segregated free list

Different free lists for different size classes

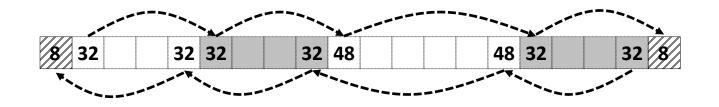

#### Method 4: Blocks sorted by size

 Can use a balanced tree (e.g. Red-Black tree) with pointers within each free block, and the length used as a key

### **Review: Boundary Tags for Coalescing**

#### Boundary tags

- Replicate size/allocated word at "bottom" (end) of free blocks
- Allows us to traverse the "list" backwards, but requires extra space
- Important and general technique!

a = 1: Allocated block a = 0: Free block

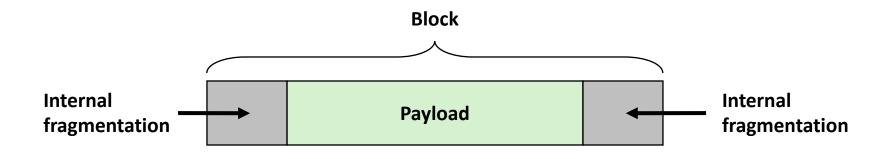

Size: Total block size

Payload: Application data (allocated blocks only)

#### **Disadvantage: Internal fragmentation**

#### **Review: Internal vs. External Fragmentation**

For a given block, internal fragmentation occurs if payload is smaller than block size

 External fragmentation occurs when there is enough aggregate heap memory, but no single free block is large enough

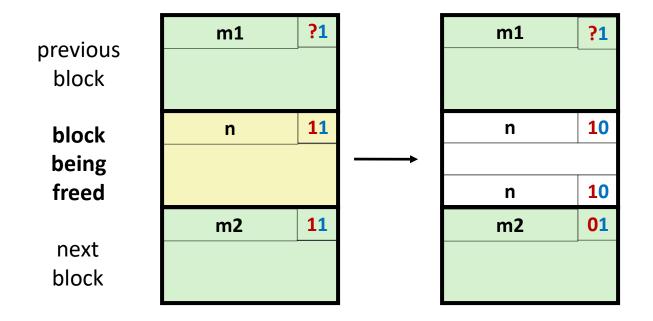

#### **Review: No Boundary Tag for Allocated Blocks**

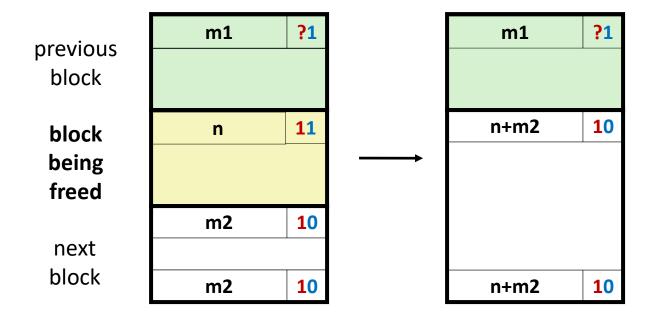

- Boundary tag needed only for free blocks
- When sizes are multiples of 16, have 4 spare bits

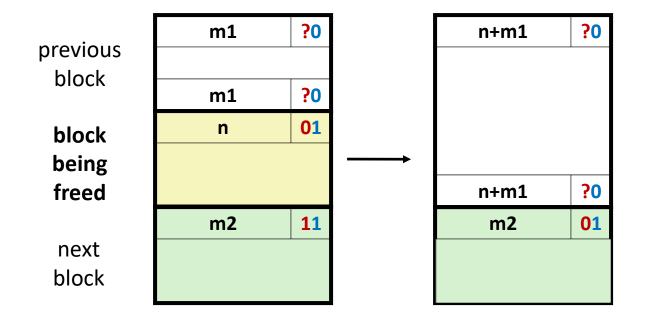

# No Boundary Tag for Allocated Blocks (Case 1)

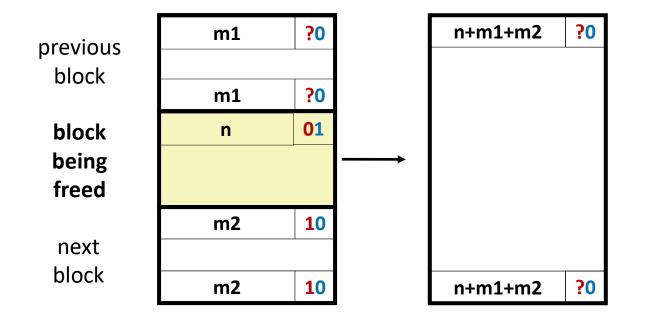

# No Boundary Tag for Allocated Blocks (Case 2)

# No Boundary Tag for Allocated Blocks (Case 3)

# No Boundary Tag for Allocated Blocks (Case 4)

# **Implicit Lists Summary**

Implementation: very simple

#### Allocate cost:

linear time worst case

#### Free cost:

- constant time worst case
- even with coalescing

#### Memory Overhead:

- Depends on placement policy
- Strategies include first fit, next fit, and best fit
- Not used in practice for malloc/free because of lineartime allocation
  - used in many special purpose applications

#### However, the concepts of splitting and boundary tag coalescing are general to *all* allocators

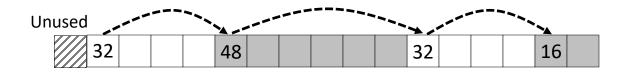

### Today

- Implicit free lists (review)
- Explicit free lists
- Segregated free lists
- Memory-related perils and pitfalls

CSAPP 9.9.13 CSAPP 9.9.14 CSAPP 9.11

#### **Keeping Track of Free Blocks**

Method 1: Implicit list using length—links all blocks

Method 2: Explicit list among the free blocks using pointers

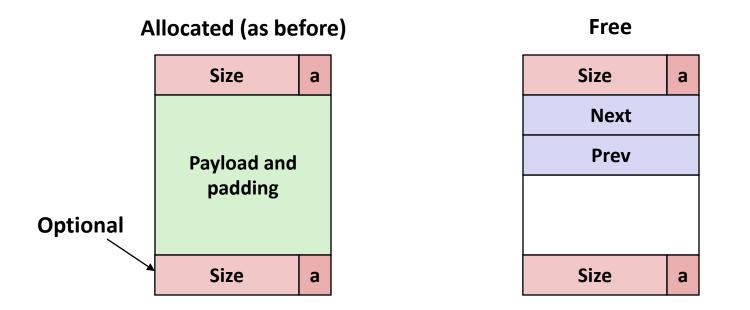

- Method 3: Segregated free list
  - Different free lists for different size classes

#### Method 4: Blocks sorted by size

 Can use a balanced tree (e.g. Red-Black tree) with pointers within each free block, and the length used as a key

#### **Explicit Free Lists**

#### Maintain list(s) of *free* blocks, not *all* blocks

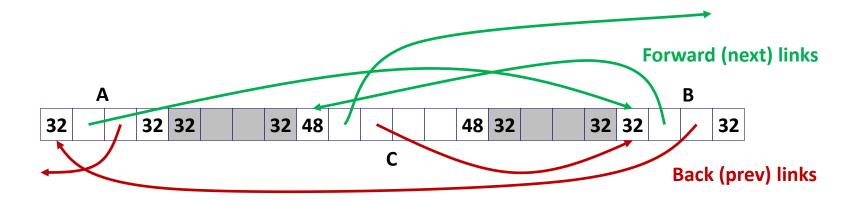

- Luckily we track only free blocks, so we can use payload area
- The "next" free block could be anywhere
  - So we need to store forward/back pointers, not just sizes
- Still need boundary tags for coalescing
  - To find adjacent blocks according to memory order

#### **Explicit Free Lists**

Logically:

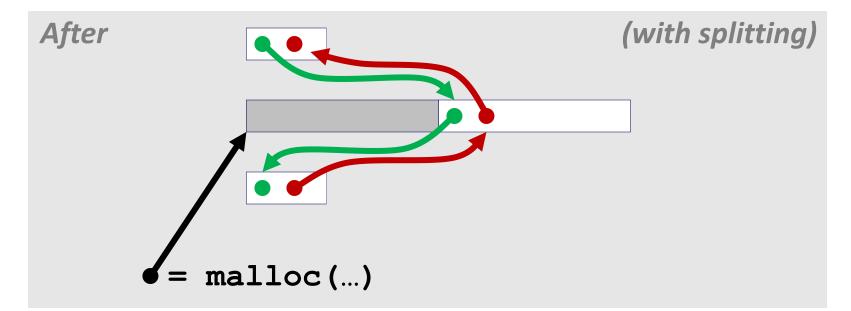

Physically: blocks can be in any order

### **Allocating From Explicit Free Lists**

conceptual graphic

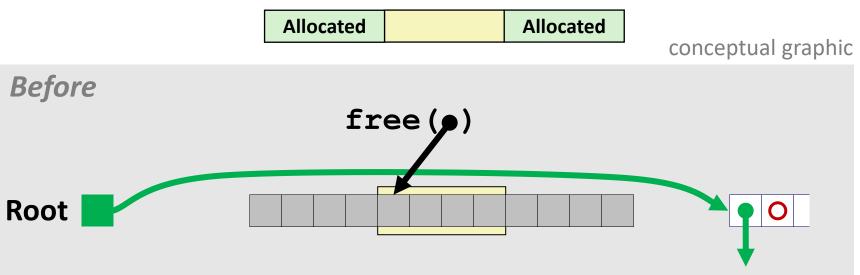

### **Freeing With Explicit Free Lists**

- Insertion policy: Where in the free list do you put a newly freed block?
- Unordered
  - LIFO (last-in-first-out) policy
    - Insert freed block at the beginning of the free list
  - FIFO (first-in-first-out) policy
    - Insert freed block at the end of the free list
  - **Pro:** simple and constant time
  - Con: studies suggest fragmentation is worse than address ordered

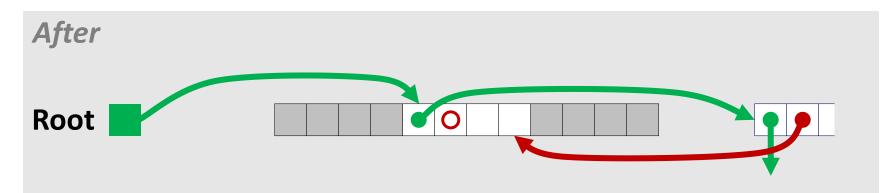

#### Address-ordered policy

- Insert freed blocks so that free list blocks are always in address order: *addr(prev) < addr(curr) < addr(next)*
- Con: requires search
- Pro: studies suggest fragmentation is lower than LIFO/FIFO

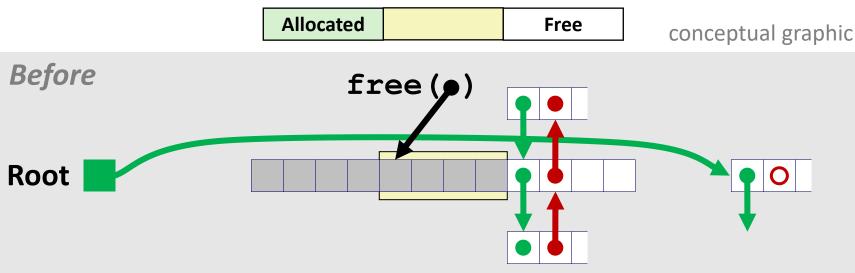

### Freeing With a LIFO Policy (Case 1)

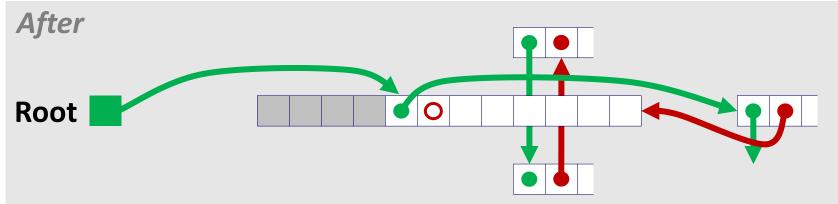

Insert the freed block at the root of the list

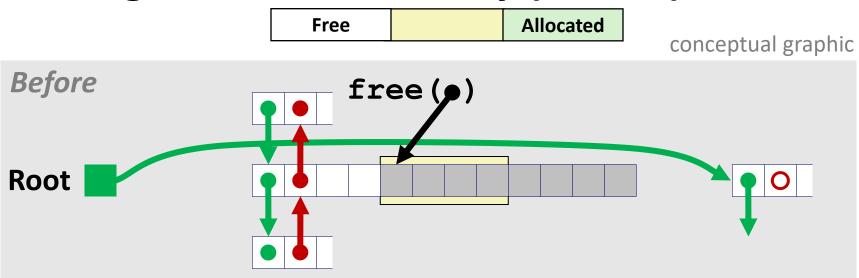

### Freeing With a LIFO Policy (Case 2)

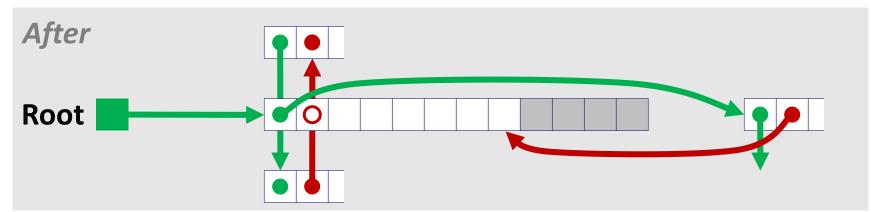

Splice out adjacent successor block, coalesce both memory blocks, and insert the new block at the root of the list

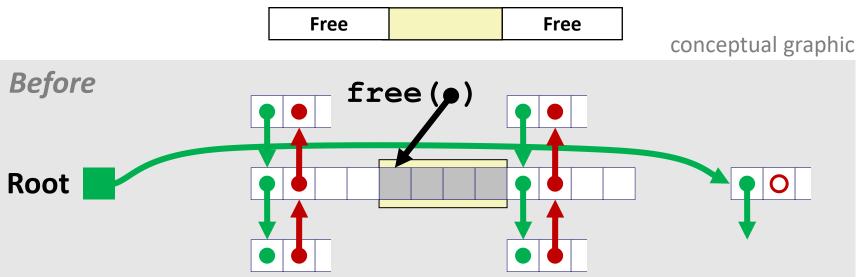

### Freeing With a LIFO Policy (Case 3)

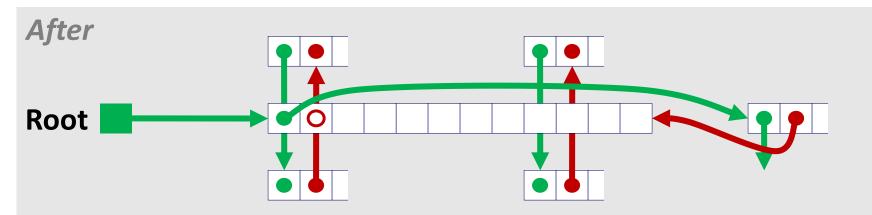

Splice out adjacent predecessor block, coalesce both memory blocks, and insert the new block at the root of the list

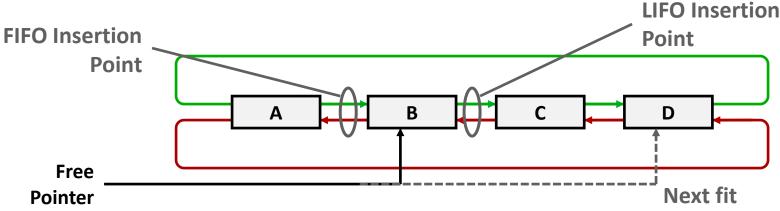

### Freeing With a LIFO Policy (Case 4)

Splice out adjacent predecessor and successor blocks, coalesce all 3 blocks, and insert the new block at the root of the list

### **Some Advice: An Implementation Trick**

- Use circular, doubly-linked list
- Support multiple approaches with single data structure
- First-fit vs. next-fit
  - Either keep free pointer fixed or move as search list
- LIFO vs. FIFO
  - Insert as next block (LIFO), or previous block (FIFO)

### **Explicit List Summary**

#### Comparison to implicit list:

- Allocate is linear time in number of *free* blocks instead of *all* blocks
  - *Much faster* when most of the memory is full
- Slightly more complicated allocate and free because need to splice blocks in and out of the list
- Some extra space for the links (2 extra words needed for each block)
  - Does this increase internal fragmentation?

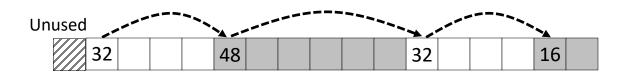

### Today

#### **Explicit free lists**

- Segregated free lists
- Memory-related perils and pitfalls

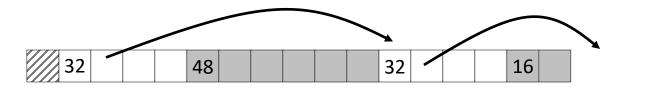

### **Keeping Track of Free Blocks**

Method 1: Implicit list using length—links all blocks

Need to tag each block as allocated/free

Method 2: Explicit list among the free blocks using pointers

Need space for pointers

Method 3: Segregated free list

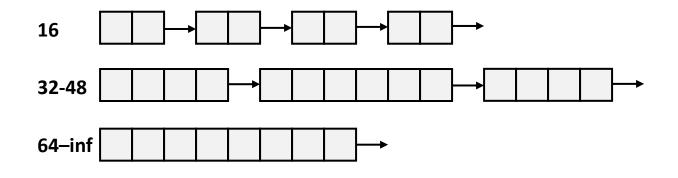

Different free lists for different size classes

#### Method 4: Blocks sorted by size

 Can use a balanced tree (e.g. Red-Black tree) with pointers within each free block, and the length used as a key

### Segregated List (Seglist) Allocators

Each *size class* of blocks has its own free list

- Often have separate classes for each small size
- For larger sizes: One class for each size  $[2^i + 1, 2^{i+1}]$

### **Seglist Allocator**

Given an array of free lists, each one for some size class

#### To allocate a block of size n:

- Search appropriate free list for block of size m > n (i.e., first fit)
- If an appropriate block is found:
  - Split block and place fragment on appropriate list
  - If no block is found, try next larger class
- Repeat until block is found

#### If no block is found:

- Request additional heap memory from OS (using sbrk())
- Allocate block of n bytes from this new memory
- Place remainder as a single free block in appropriate size class.

### Seglist Allocator (cont.)

#### To free a block:

- Coalesce and place on appropriate list
- Advantages of seglist allocators vs. non-seglist allocators (both with first-fit)
  - Higher throughput
    - log time for power-of-two size classes vs. linear time
  - Better memory utilization
    - First-fit search of segregated free list approximates a best-fit search of entire heap.
    - Extreme case: Giving each block its own size class is equivalent to best-fit.

### **More Info on Allocators**

 D. Knuth, The Art of Computer Programming, vol 1, 3<sup>rd</sup> edition, Addison Wesley, 1997

The classic reference on dynamic storage allocation

Wilson et al, "Dynamic Storage Allocation: A Survey and Critical Review", Proc. 1995 Int'l Workshop on Memory Management, Kinross, Scotland, Sept, 1995.

- Comprehensive survey
- Available from CS:APP student site (csapp.cs.cmu.edu)

#### Quiz Time!

#### Canvas Quiz: Day 15 – Malloc Advanced

### Today

- **Explicit free lists**
- Segregated free lists
- Memory-related perils and pitfalls

### **Memory-Related Perils and Pitfalls**

- Dereferencing bad pointers
- Reading uninitialized memory
- Overwriting memory
- Referencing nonexistent variables
- Freeing blocks multiple times
- Referencing freed blocks
- Failing to free blocks

#### **Dereferencing Bad Pointers**

The classic scanf bug

int val; ... scanf("%d", val);

## **Reading Uninitialized Memory**

Assuming that heap data is initialized to zero

```
/* return y = Ax */
int *matvec(int **A, int *x) {
    int *y = malloc(N*sizeof(int));
    int i, j;
    for (i=0; i<N; i++)
        for (j=0; j<N; j++)
            y[i] += A[i][j]*x[j];
    return y;
}</pre>
```

#### Can avoid by using calloc

### **Overwriting Memory**

Allocating the (possibly) wrong sized object

```
int **p;
p = malloc(N*sizeof(int));
for (i=0; i<N; i++) {
    p[i] = malloc(M*sizeof(int));
}
```

#### Can you spot the bug?

#### Off-by-one errors

```
char **p;
p = malloc(N*sizeof(int *));
for (i=0; i<=N; i++) {
    p[i] = malloc(M*sizeof(int));
}
```

```
char *p;
p = malloc(strlen(s));
strcpy(p,s);
```

Not checking the max string size

```
char s[8];
int i;
gets(s); /* reads "123456789" from stdin */
```

Basis for classic buffer overflow attacks

Misunderstanding pointer arithmetic

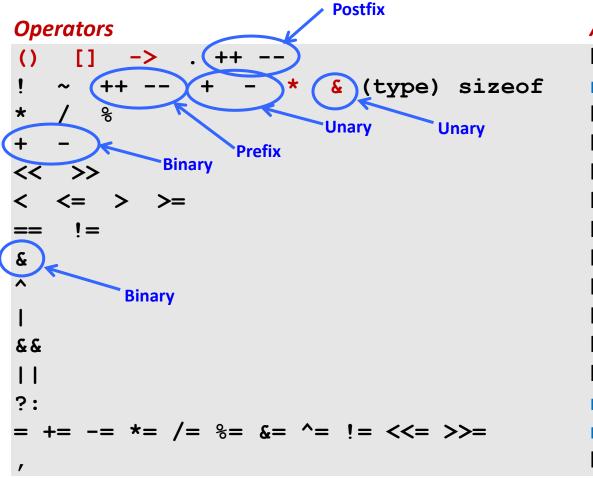

```
int *search(int *p, int val) {
  while (p && *p != val)
     p += sizeof(int);
  return p;
}
```

Referencing a pointer instead of the object it points to

```
int *BinheapDelete(int **binheap, int *size) {
    int *packet;
    packet = binheap[0];
    binheap[0] = binheap[*size - 1];
    *size--;
    Heapify(binheap, *size, 0);
    return(packet);
}
```

- What gets decremented?
  - (See next slide)

### **C** operators

Associativity left to right right to left left to right right to left right to left left to right

# ->, (), and [] have high precedence, with \* and & just below Unary +, -, and \* have higher precedence than binary forms

Source: K&R page 53, updated 41

Referencing a pointer instead of the object it points to

```
int *BinheapDelete(int **binheap, int *size) {
         int *packet;
         packet = binheap[0];
         binheap[0] = binheap[*size - 1];
         *size--;
         Heapify(binheap, *size, 0);
         return (packet) ;
                                           Operators
                                                                               Associativity
     }
                                                                                left to right
                                            ()
                                              [1
                                                                 (type) sizeof
                                                                                right to left
                                                                                left to right
                                            *
                                                 ℅
                                                                                left to right
                                            +
Same effect as
                                                                                left to right
                                           << >>
                                            < <= > >=
                                                                                left to right
                                               !=
                                                                               left to right
                                            ==
    size--;
                                                                               left to right
                                            &
                                            ^
                                                                               left to right
Rewrite as
                                                                               left to right
                                                                               left to right
                                            88
    (*size)--;
                                            11
                                                                               left to right
                                                                                right to left
                                            ?:
                                            = += -= *= /= %= &= ^= != <<= >>=
                                                                                right to left
                                                                               left to right
```

### **Referencing Nonexistent Variables**

Forgetting that local variables disappear when a function returns

```
int *foo () {
    int val;
    return &val;
}
```

### **Freeing Blocks Multiple Times**

#### Nasty!

### **Referencing Freed Blocks**

#### Evil!

### Failing to Free Blocks (Memory Leaks)

Slow, long-term killer!

```
foo() {
    int *x = malloc(N*sizeof(int));
    ...
    return;
}
```

### Failing to Free Blocks (Memory Leaks)

Freeing only part of a data structure

```
struct list {
   int val;
   struct list *next;
};
foo() {
   struct list *head = malloc(sizeof(struct list));
   head \rightarrow val = 0;
   head->next = NULL;
   <create and manipulate the rest of the list>
    . . .
   free(head);
   return;
}
```

## **Dealing With Memory Bugs**

#### Debugger: gdb

- Good for finding bad pointer dereferences
- Hard to detect the other memory bugs

#### Data structure consistency checker

- Runs silently, prints message only on error
- Use as a probe to zero in on error

#### Binary translator: valgrind

- Powerful debugging and analysis technique
- Rewrites text section of executable object file
- Checks each individual reference at runtime
  - Bad pointers, overwrites, refs outside of allocated block

### glibc malloc contains checking code

setenv MALLOC\_CHECK\_ 3

### **Supplemental slides**

### **Implicit Memory Management:** Garbage Collection

 Garbage collection: automatic reclamation of heap-allocated storage—application never has to explicitly free memory

```
void foo() {
    int *p = malloc(128);
    return; /* p block is now garbage */
}
```

#### Common in many dynamic languages:

Python, Ruby, Java, Perl, ML, Lisp, Mathematica

#### Variants ("conservative" garbage collectors) exist for C and C++

However, cannot necessarily collect all garbage

### **Garbage Collection**

- How does the memory manager know when memory can be freed?
  - In general we cannot know what is going to be used in the future since it depends on conditionals
  - But we can tell that certain blocks cannot be used if there are no pointers to them

#### Must make certain assumptions about pointers

- Memory manager can distinguish pointers from non-pointers
- All pointers point to the start of a block
- Cannot hide pointers

   (e.g., by coercing them to an int, and then back again)

# **Classical GC Algorithms**

#### Mark-and-sweep collection (McCarthy, 1960)

Does not move blocks (unless you also "compact")

### Reference counting (Collins, 1960)

Does not move blocks (not discussed)

### Copying collection (Minsky, 1963)

Moves blocks (not discussed)

### Generational Collectors (Lieberman and Hewitt, 1983)

- Collection based on lifetimes
  - Most allocations become garbage very soon
  - So focus reclamation work on zones of memory recently allocated

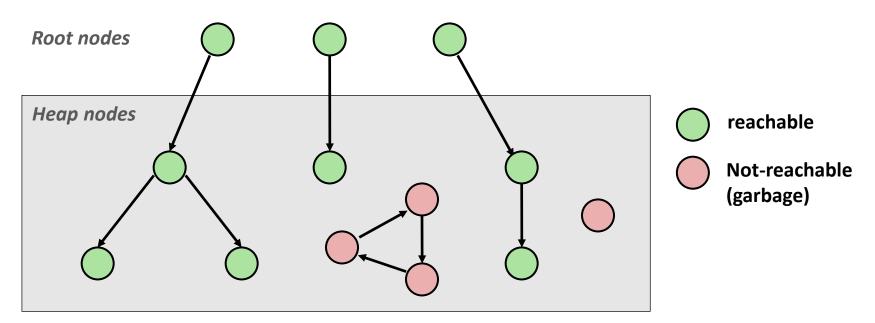

#### For more information:

Jones and Lin, "Garbage Collection: Algorithms for Automatic Dynamic Memory", John Wiley & Sons, 1996.

### Memory as a Graph

#### We view memory as a directed graph

- Each block is a node in the graph
- Each pointer is an edge in the graph
- Locations not in the heap that contain pointers into the heap are called root nodes (e.g. registers, locations on the stack, global variables)

#### A node (block) is *reachable* if there is a path from any root to that node.

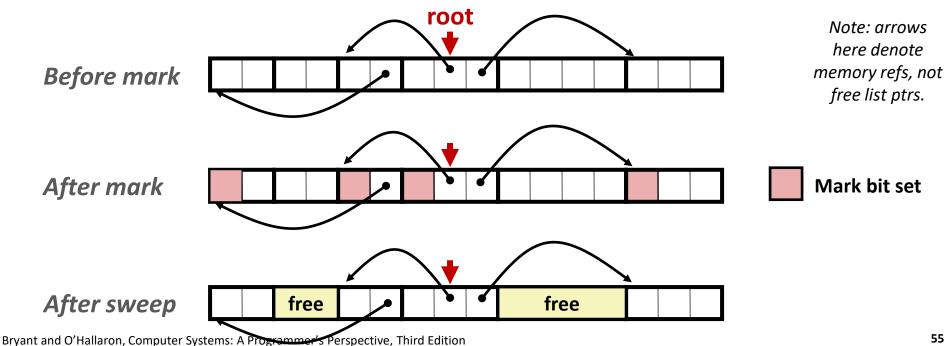

#### Non-reachable nodes are *garbage* (cannot be needed by the application)

### Mark and Sweep Collecting

- Can build on top of malloc/free package
  - Allocate using **malloc** until you "run out of space"

#### When out of space:

- Use extra **mark bit** in the head of each block
- *Mark*: Start at roots and set mark bit on each reachable block
- **Sweep:** Scan all blocks and free blocks that are not marked

### **Assumptions For a Simple Implementation**

#### Application

- **new(n):** returns pointer to new block with all locations cleared
- read(b,i): read location i of block b into register
- write(b,i,v): write v into location i of block b

#### Each block will have a header word

- addressed as b[-1], for a block b
- Used for different purposes in different collectors
- Instructions used by the Garbage Collector
  - is\_ptr(p): determines whether p is a pointer
  - length (b): returns the length of block b, not including the header
  - get\_roots(): returns all the roots

```
ptr mark(ptr p) {
    if (!is_ptr(p)) return;
    if (markBitSet(p)) return;
    setMarkBit(p);
    for (i=0; i < length(p); i++)
        mark(p[i]);
    return;
}</pre>
```

```
ptr mark(ptr p) {
    if (!is_ptr(p)) return; // if not pointer -> do nothing
    if (markBitSet(p)) return;
    setMarkBit(p);
    for (i=0; i < length(p); i++)
       mark(p[i]);
    return;
}</pre>
```

```
ptr mark(ptr p) {
    if (!is_ptr(p)) return; // if not pointer -> do nothing
    if (markBitSet(p)) return; // if already marked -> do nothing
    setMarkBit(p);
    for (i=0; i < length(p); i++)
        mark(p[i]);
    return;
}</pre>
```

```
ptr mark(ptr p) {
    if (!is_ptr(p)) return; // if not pointer -> do nothing
    if (markBitSet(p)) return; // if already marked -> do nothing
    setMarkBit(p); // set the mark bit
    for (i=0; i < length(p); i++)
        mark(p[i]);
    return;
}</pre>
```

```
ptr mark(ptr p) {
    if (!is_ptr(p)) return; // if not pointer -> do nothing
    if (markBitSet(p)) return; // if already marked -> do nothing
    setMarkBit(p); // set the mark bit
    for (i=0; i < length(p); i++) // for each word in p's block
        mark(p[i]);
    return;
}</pre>
```

```
ptr mark(ptr p) {
    if (!is_ptr(p)) return; // if not pointer -> do nothing
    if (markBitSet(p)) return; // if already marked -> do nothing
    setMarkBit(p); // set the mark bit
    for (i=0; i < length(p); i++) // for each word in p's block
        mark(p[i]); // make recursive call
    return;
}</pre>
```

Mark using depth-first traversal of the memory graph

```
ptr mark(ptr p) {
    if (!is_ptr(p)) return; // if not pointer -> do nothing
    if (markBitSet(p)) return; // if already marked -> do nothing
    setMarkBit(p); // set the mark bit
    for (i=0; i < length(p); i++) // for each word in p's block
        mark(p[i]); // make recursive call
    return;
}</pre>
```

Sweep using lengths to find next block

```
ptr sweep(ptr p, ptr end) {
  while (p < end) { // for entire heap
      if markBitSet(p)
         clearMarkBit();
      else if (allocateBitSet(p))
         free(p);
         p += length(p+1);
}</pre>
```

Mark using depth-first traversal of the memory graph

Sweep using lengths to find next block

```
ptr sweep(ptr p, ptr end) {
  while (p < end) { // for entire heap
    if markBitSet(p) // did we reach this block?
        clearMarkBit();
    else if (allocateBitSet(p))
        free(p);
        p += length(p+1);
}</pre>
```

Mark using depth-first traversal of the memory graph

Sweep using lengths to find next block

Mark using depth-first traversal of the memory graph

Sweep using lengths to find next block

Mark using depth-first traversal of the memory graph

Sweep using lengths to find next block

```
ptr sweep(ptr p, ptr end) {
  while (p < end) { // for entire heap
    if markBitSet(p) // did we reach this block?
        clearMarkBit(); // yes -> so just clear mark bit
    else if (allocateBitSet(p)) // never reached: is it allocated?
        free(p); // yes -> its garbage, free it
        p += length(p+1);
}
```

Mark using depth-first traversal of the memory graph

Sweep using lengths to find next block

```
ptr sweep(ptr p, ptr end) {
  while (p < end) { // for entire heap
    if markBitSet(p) // did we reach this block?
        clearMarkBit(); // yes -> so just clear mark bit
    else if (allocateBitSet(p)) // never reached: is it allocated?
        free(p); // yes -> its garbage, free it
        p += length(p+1); // goto next block
```

### **C** Pointer Declarations: Test Yourself!

int	*p	p is a pointer to int
int	*p[13]	p is an array[13] of pointer to int
int	*(p[13])	p is an array[13] of pointer to int
int	**p	p is a pointer to a pointer to an int
int	(*p) [13]	p is a pointer to an array[13] of int
int	*f()	f is a function returning a pointer to int
int	(*f)()	f is a pointer to a function returning int
int	(*(*x[3])())[5]	x is an array[3] of pointers to functions returning pointers to array[5] of ints

70

### **C** Pointer Declarations: Test Yourself!

int	*p	p is a pointer to int
int	*p[13]	p is an array[13] of pointer to int
int	*(p[13])	p is an array[13] of pointer to int
int	**p	p is a pointer to a pointer to an int
int	(*p) [13]	p is a pointer to an array[13] of int
int	*f()	f is a function returning a pointer to int
int	(*f)()	f is a pointer to a function returning int
int	(*(*x[3])())[5]	x is an array[3] of pointers to functions returning pointers to array[5] of ints
int	(*(*f())[13])()	f is a function returning ptr to an array[13] of pointers to functions returning int

Source: K&R Sec 5.12

### Parsing: int (\*(\*f())[13])()

f

int (\*(\*<mark>f</mark>())[13])()

```
int (*(*<mark>f()</mark>)[13])()
```

int (\*(\*f())[13])()

int (\*(\*f())[13])()

int (\*(\*f())[13])()

int (\*(\*f())[13])()

- f is a function
  - f is a function that returns a ptr

f is a function that returns a ptr to an array of 13

f is a function that returns a ptr to an array of 13 ptrs

f is a function that returns a ptr to an array of 13 ptrs to functions returning an int
