

# The Memory Hierarchy

18-213/18-613: Introduction to Computer Systems  
9<sup>th</sup> Lecture, June 1<sup>st</sup>, 2023

# Today

- **The memory abstraction**
- RAM : main memory building block
- Locality of reference
- The memory hierarchy
- Storage technologies and trends

# Writing & Reading Memory

## ■ Write

- Transfer data from CPU to memory

```
movq %rax, 8(%rsp)
```

- “Store” operation

## ■ Read

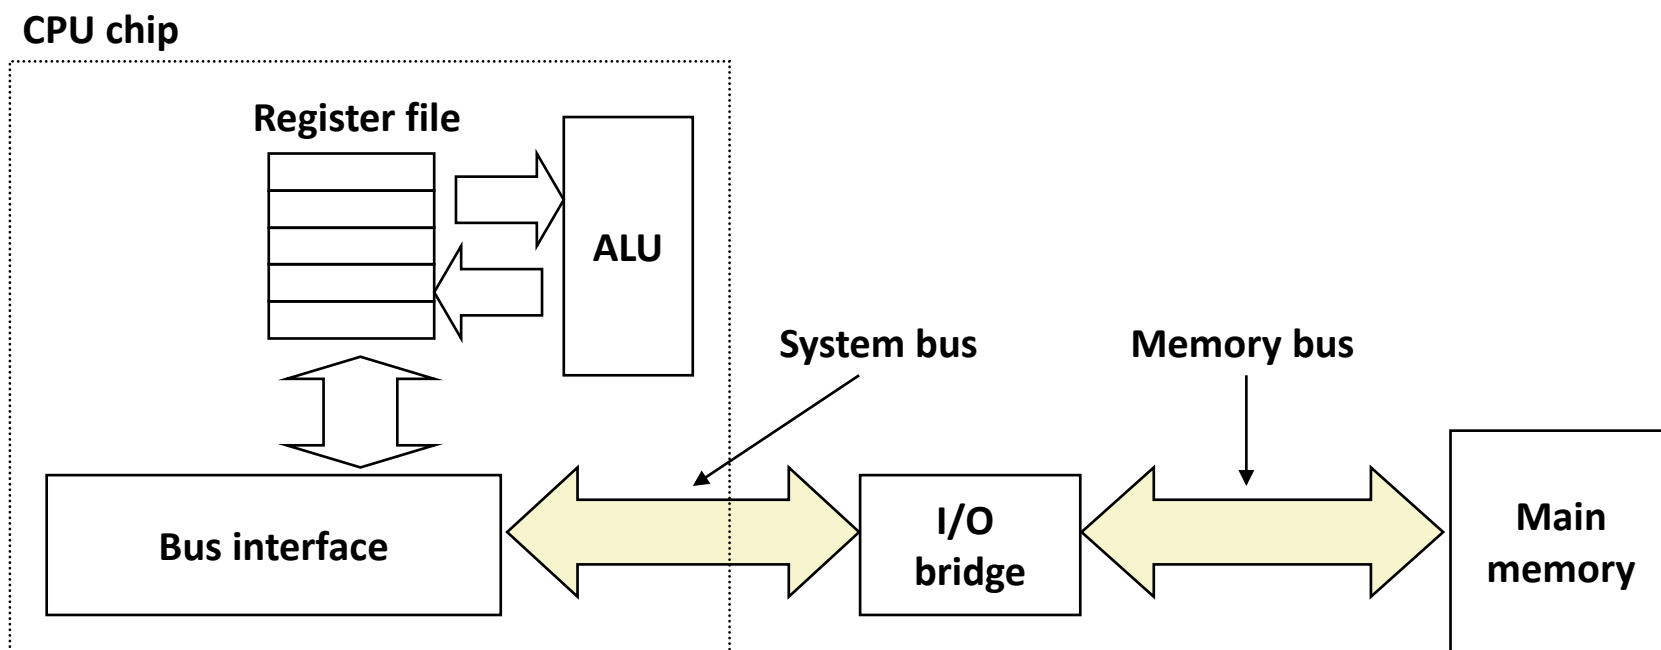

- Transfer data from memory to CPU

```
movq 8(%rsp), %rax
```

- “Load” operation

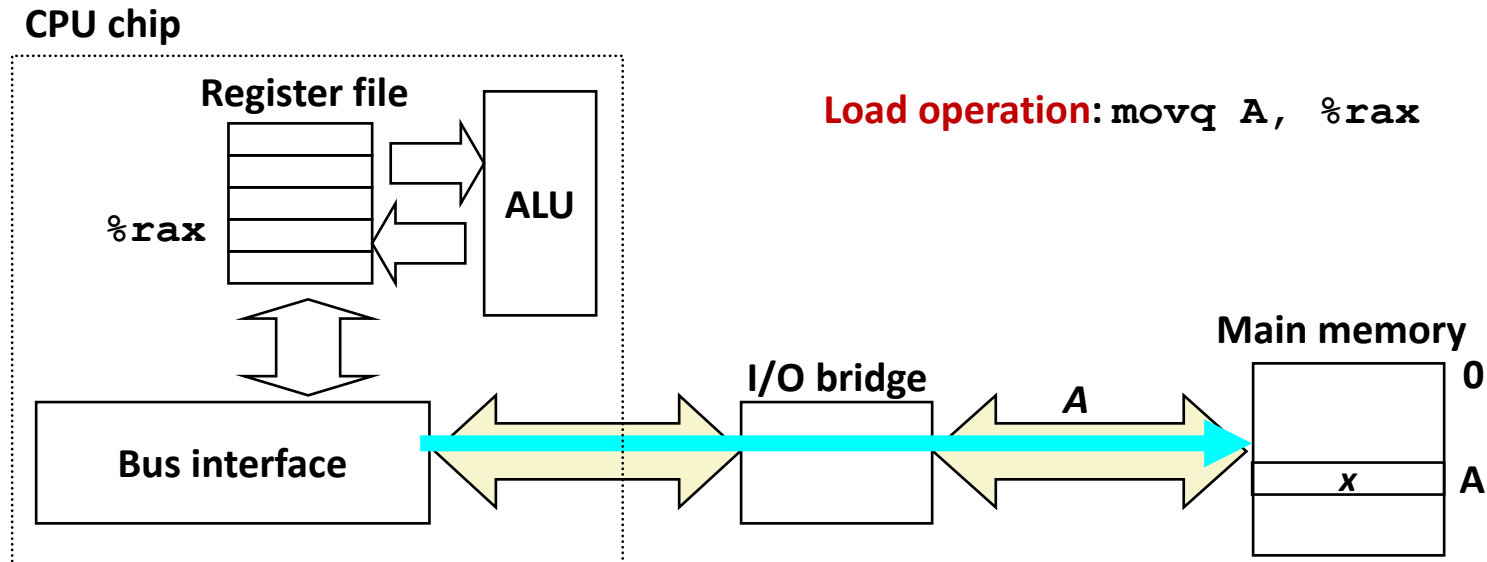

# Traditional Bus Structure Connecting CPU and Memory

- A **bus** is a collection of parallel wires that carry address, data, and control signals.
- Buses are typically shared by multiple devices.

# Memory Read Transaction (1)

- CPU places address  $A$  on the memory bus.

# Memory Read Transaction (2)

- Main memory reads  $A$  from the memory bus, retrieves word  $x$ , and places it on the bus.

# Memory Read Transaction (3)

- CPU read word  $x$  from the bus and copies it into register `%rax`.

# Memory Write Transaction (1)

- CPU places address  $A$  on bus. Main memory reads it and waits for the corresponding data word to arrive.

# Memory Write Transaction (2)

- CPU places data word  $y$  on the bus.

# Memory Write Transaction (3)

- Main memory reads data word  $y$  from the bus and stores it at address  $A$ .

# Today

- The memory abstraction
- **RAM : main memory building block**
- Locality of reference
- The memory hierarchy
- Storage technologies and trends

# Random-Access Memory (RAM)

## ■ Key features

- **RAM** is traditionally packaged as a chip.
  - or embedded as part of processor chip
- Basic storage unit is normally a **cell** (one bit per cell).
- Multiple RAM chips form a memory.

## ■ RAM comes in two varieties:

- SRAM (Static RAM)
- DRAM (Dynamic RAM)

# RAM Technologies

## ■ DRAM

- **1 Transistor + 1 capacitor / bit**
  - Capacitor oriented vertically
- **Must refresh state periodically**

## ■ SRAM

- **6 transistors / bit**
- **Holds state indefinitely (but will still lose data on power loss)**

# SRAM vs DRAM Summary

	Trans. per bit	Access time	Needs refresh?	Needs EDC?	Cost	Applications
SRAM	6 or 8	1x	No	Maybe	100x	Cache memories
DRAM	1	10x	Yes	Yes	1x	Main memories, frame buffers

EDC: Error detection and correction

## ■ Trends

- SRAM scales with semiconductor technology
  - Reaching its limits
- DRAM scaling limited by need for minimum capacitance
  - Aspect ratio limits how deep can make capacitor
  - Also reaching its limits

# Enhanced DRAMs

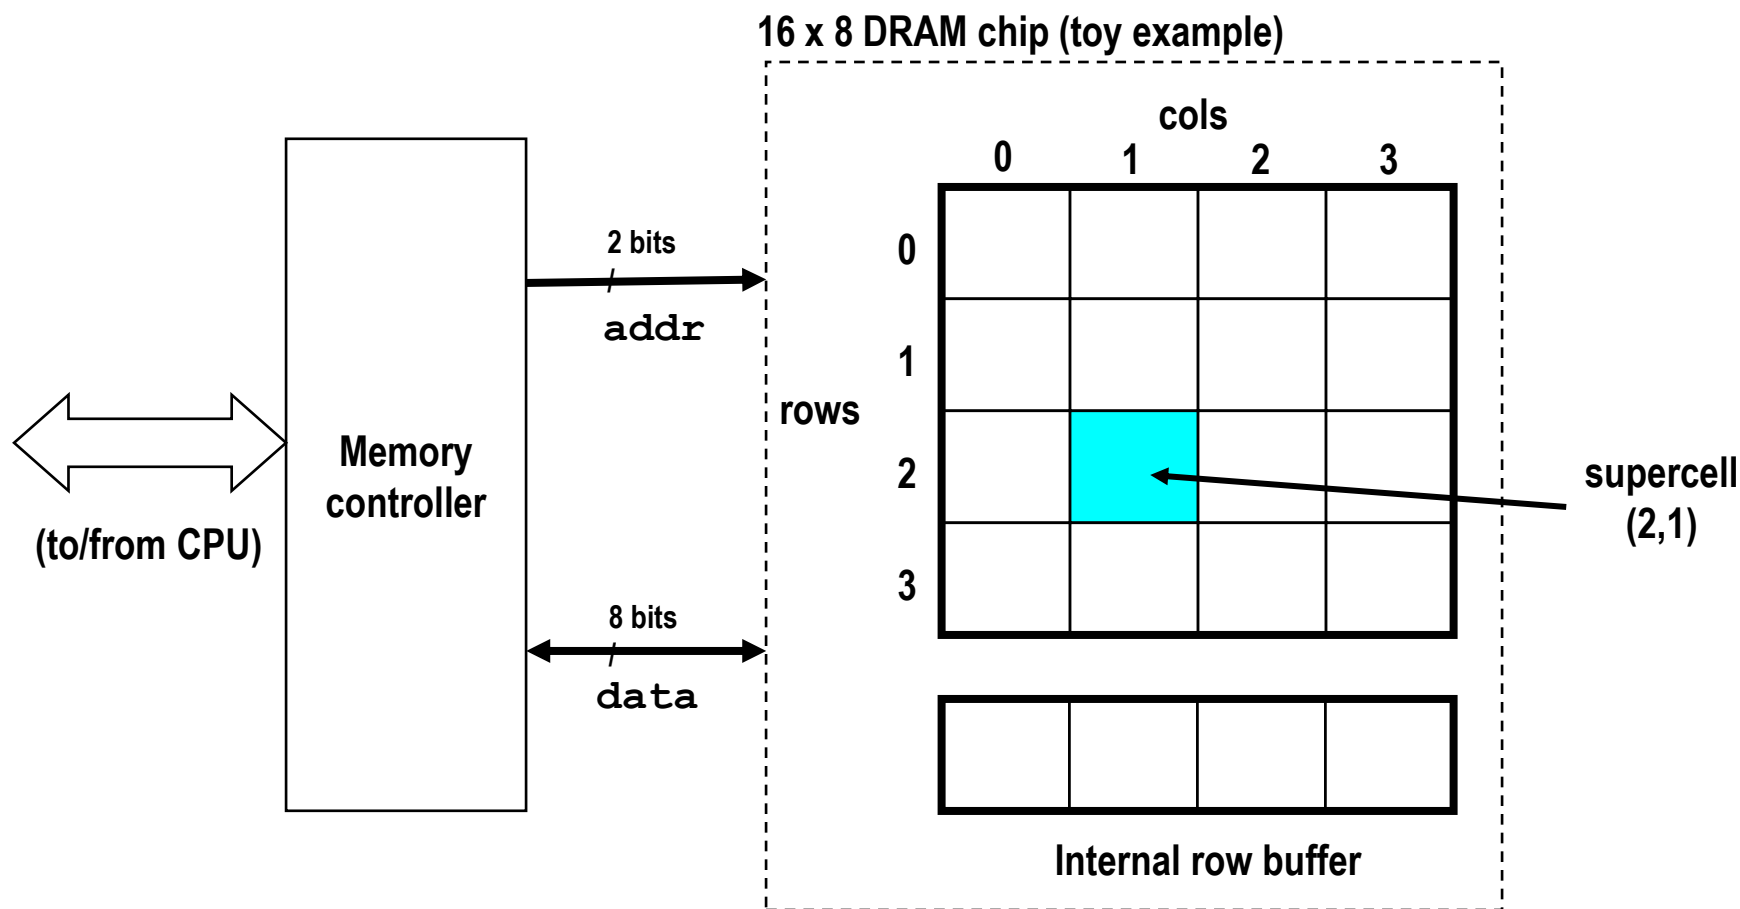

- **Operation of DRAM cell has not changed since its invention**
  - Commercialized by Intel in 1970.
- **DRAM cores with better interface logic and faster I/O :**
  - Synchronous DRAM (**SDRAM**)
    - Uses a conventional clock signal instead of asynchronous control
  - Double data-rate synchronous DRAM (**DDR SDRAM**)
    - Double edge clocking sends two bits per cycle per pin
    - Different types distinguished by size of small prefetch buffer:
      - **DDR** (2 bits), **DDR2** (4 bits), **DDR3** (8 bits), **DDR4** (16 bits)
    - By 2010, standard for most server and desktop systems
    - Intel Core i7 supports DDR3 and DDR4 SDRAM

# Conventional DRAM Organization

## ■ $d \times w$ DRAM:

- $d \cdot w$  total bits organized as  $d$  **supercells** of size  $w$  bits

# Reading DRAM Supercell (2,1)

Step 1(a): Row access strobe (**RAS**) selects row 2.

Step 1(b): Row 2 copied from DRAM array to row buffer.

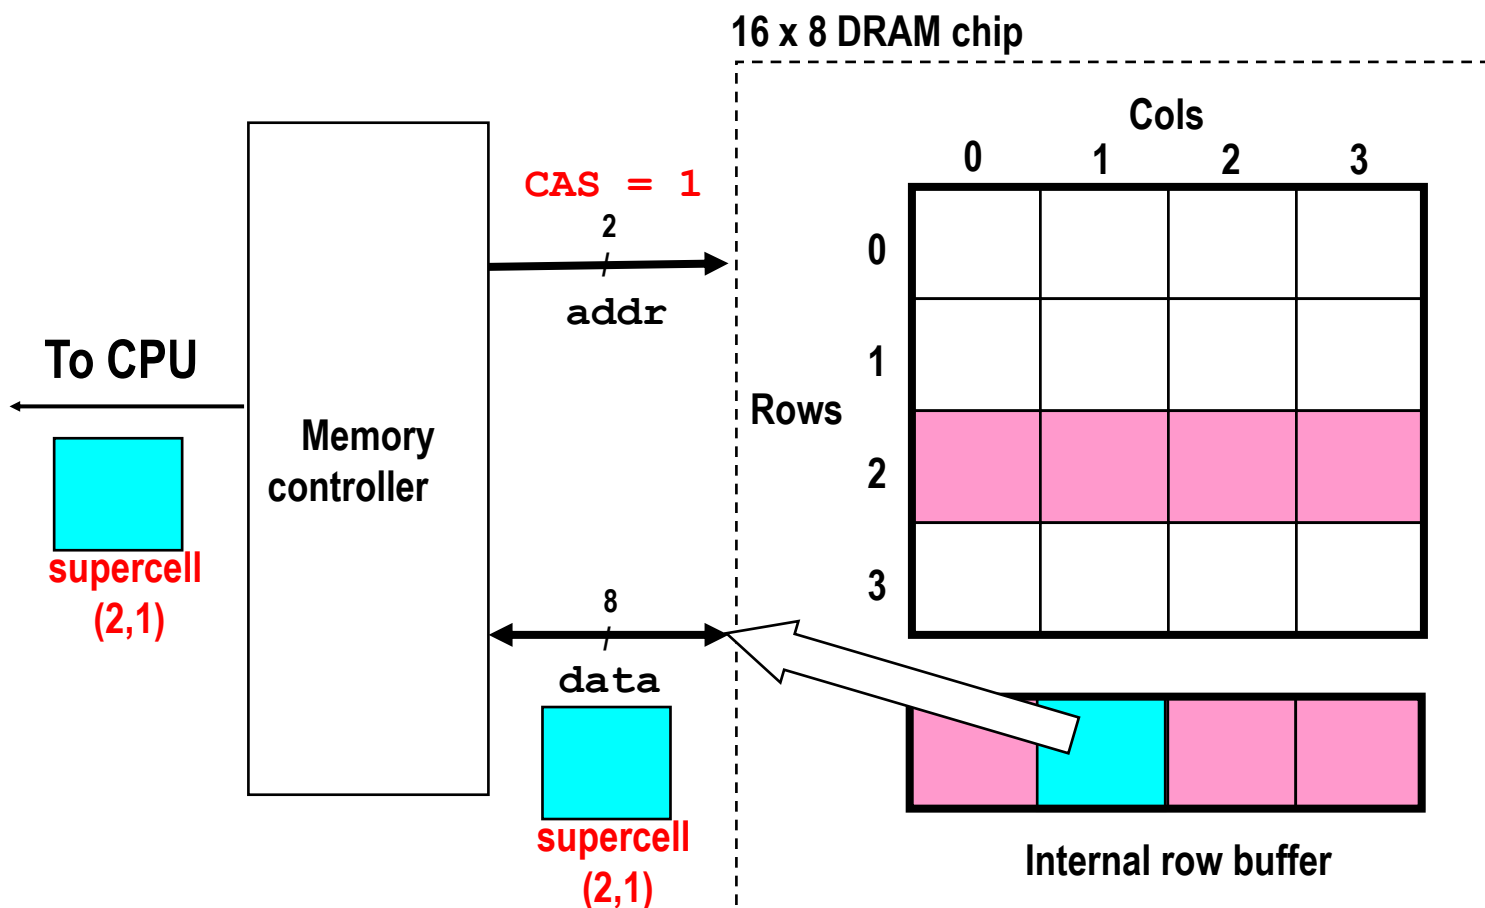

# Reading DRAM Supercell (2,1)

Step 2(a): Column access strobe (**CAS**) selects column 1.

Step 2(b): Supercell (2,1) copied from buffer to data lines, and eventually back to the CPU.

Step 3: All data written back to row to provide refresh

# Memory Modules

# Today

- The memory Abstraction
- DRAM : main memory building block
- **Locality of reference**
- The memory hierarchy
- Storage technologies and trends

# The CPU-Memory Gap

The gap *widens* between DRAM, disk, and CPU speeds.

# Memory Hierarchies

- **Some fundamental and enduring properties of hardware and software:**
  - Fast storage technologies cost more per byte, have less capacity, and require more power (heat!).
  - The gap between CPU and main memory speed is widening.
  - Well-written programs tend to exhibit good locality.
- **These fundamental properties complement each other beautifully.**
- **They suggest an approach for organizing memory and storage systems known as a **memory hierarchy**.**

# Example Memory Hierarchy

# How to leverage the hierarchy?

- **What if we could keep the data that is presently being used in the fastest memory at the top of the hierarchy.**
  - And use the lower layers, that have more capacity and are cheaper, but slower to store the things that we aren't using right now
- **Then we'd be working at the speed of the fastest storage**
  - But since we use relatively little of the data at any time, we'd be able to store most of what we need over the long haul in the cheapest memory
- **On average, we'd be working very close to the speed of the fastest memory, but paying, on average, for storage at a price-per-byte very close to the cheapest memory in the system**
  - The cost of moving the data to and from the slower layer is amortized to something negligible over many, many accesses at the higher layer.

# The Working Set

- The data that is presently being use is called the *Working Set*.
- Imagine you are working on 18x13. Your working set might include:
  - The lab handout
  - A terminal window for editing
  - A terminal window for debugging
  - A browser window for looking up man pages
- If you changed tasks, you'd probably hide those windows and open new ones
- The data computer programs use works the same way.

# Finding (Guesstimating) the Working Set

- **How does the memory system (cache logic) know the working set?**
  - This is tricky. There is no way it can really know what data the program needs or will need soon.
  - It could even be totally dynamic, based upon input.
- **It approximates it using a simple heuristic called *locality*:**
  - *Temporal locality*: Data used recently is likely to be used again in the near future (local in time).
  - *Spatial locality*: Data near the data used recently is likely to be used soon (local in space, e.g. address space).
- **The memory system will bring and keep the *Most Recently Used (MRU)* data and data near it in memory to the higher layers while evicting the *Least Recently Used (LRU)* data to the lower layers.**

# Locality

- **Principle of Locality:** Programs tend to use data and instructions with addresses near or equal to those they have used recently

- **Temporal locality:**

- Recently referenced items are likely to be referenced again in the near future

- **Spatial locality:**

- Items with nearby addresses tend to be referenced close together in time

# Locality Example

```
sum = 0;
for (i = 0; i < n; i++)
    sum += a[i];
return sum;
```

## ■ Data references

- Reference array elements in succession (**stride-1 reference pattern**).
- Reference variable **sum** each iteration.

## ■ Instruction references

- Reference instructions in sequence.
- Cycle through loop repeatedly.

## Spatial or Temporal Locality?

**spatial**

**temporal**

**spatial**

**temporal**

# Qualitative Estimates of Locality

- **Claim:** Being able to look at code and get a qualitative sense of its locality is a key skill for a professional programmer.
- **Question:** Does this function have good locality with respect to array *a*?

Hint: array layout  
is row-major order

Answer: yes  
Stride-1 reference  
pattern

```
int sum_array_rows(int a[M][N])
{
    int i, j, sum = 0;

    for (i = 0; i < M; i++)
        for (j = 0; j < N; j++)
            sum += a[i][j];

    return sum;
}
```

a		a	a		a		a		a
[0]	...	[0]	[1]	...	[1]	...	[M-1]	...	[M-1]
[0]		[N-1]	[0]		[N-1]		[0]		[N-1]

# Locality Example

- **Question:** Does this function have good locality with respect to array `a`?

```
int sum_array_cols(int a[M][N])
{
    int i, j, sum = 0;

    for (j = 0; j < N; j++)
        for (i = 0; i < M; i++)
            sum += a[i][j];
    return sum;
}
```

**Answer: no**

**Stride N reference  
pattern**

**Note: If M is very small  
then good locality. Why?**

# Locality Example

- **Question:** Can you permute the loops so that the function scans the 3-d array `a` with a stride-1 reference pattern (and thus has good spatial locality)?

```
int sum_array_3d(int a[M][N][N])
{
    int i, j, k, sum = 0;

    for (i = 0; i < N; i++)
        for (j = 0; j < N; j++)
            for (k = 0; k < M; k++)
                sum += a[k][i][j];

    return sum;
}
```

```
$ time ./loopijk
real    0m2.765s
user    0m2.328s
sys     0m0.422s
```

```
$ time ./loopkij
real    0m1.651s
user    0m1.234s
sys     0m0.422s
```

**Answer: make `j` the inner loop**

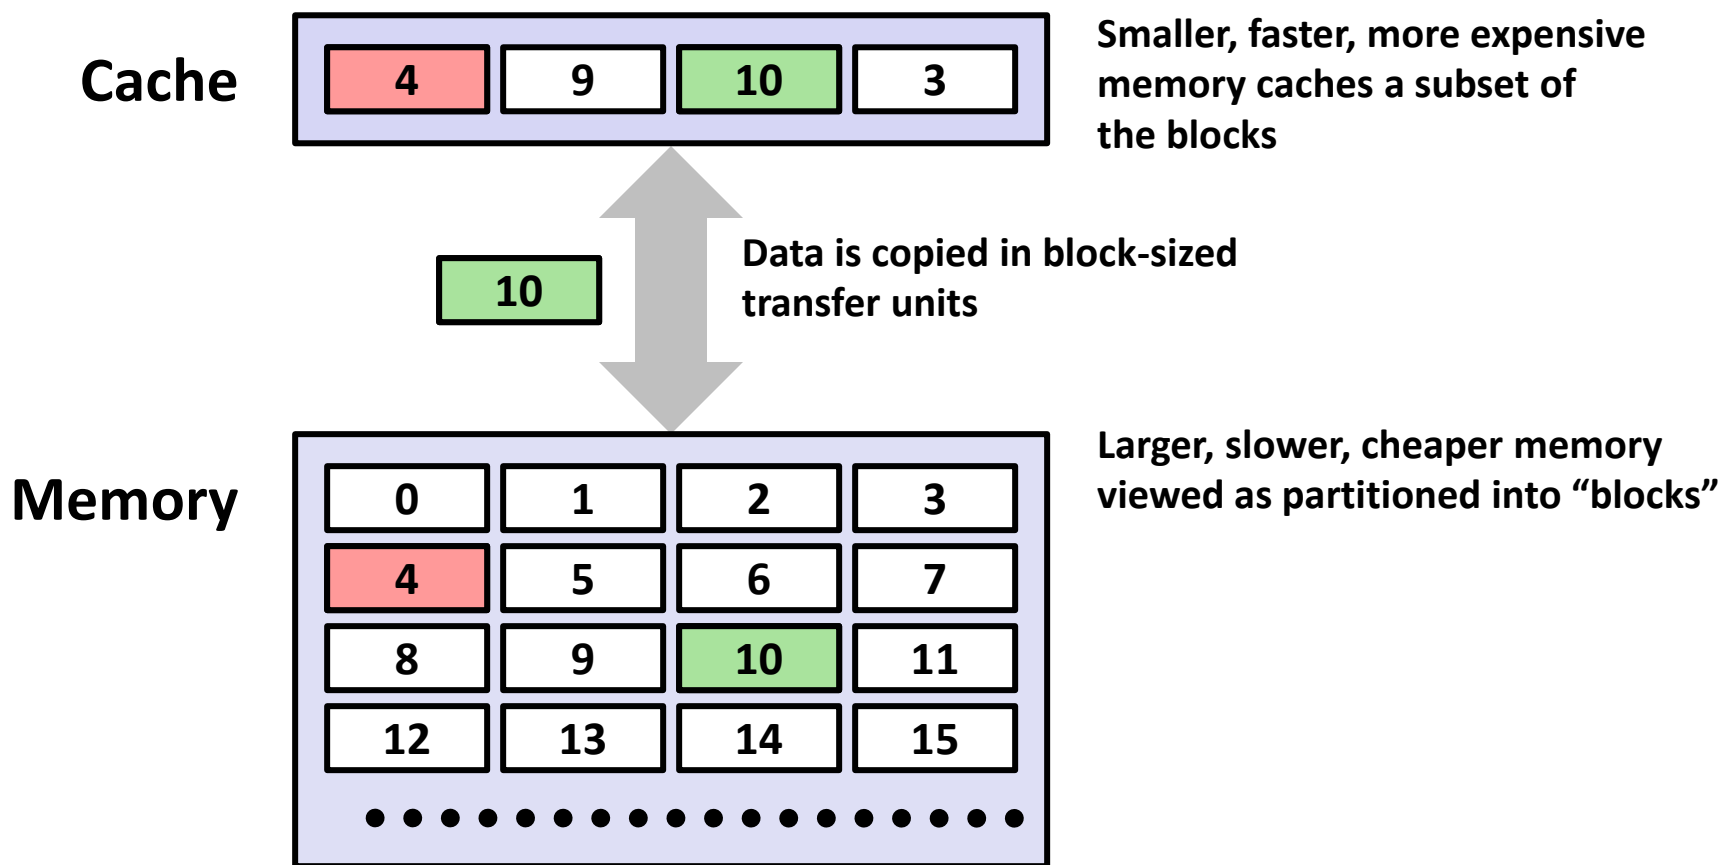

# Today

- The memory abstraction
- DRAM : main memory building block
- Locality of reference
- **The memory hierarchy**
- Storage technologies and trends

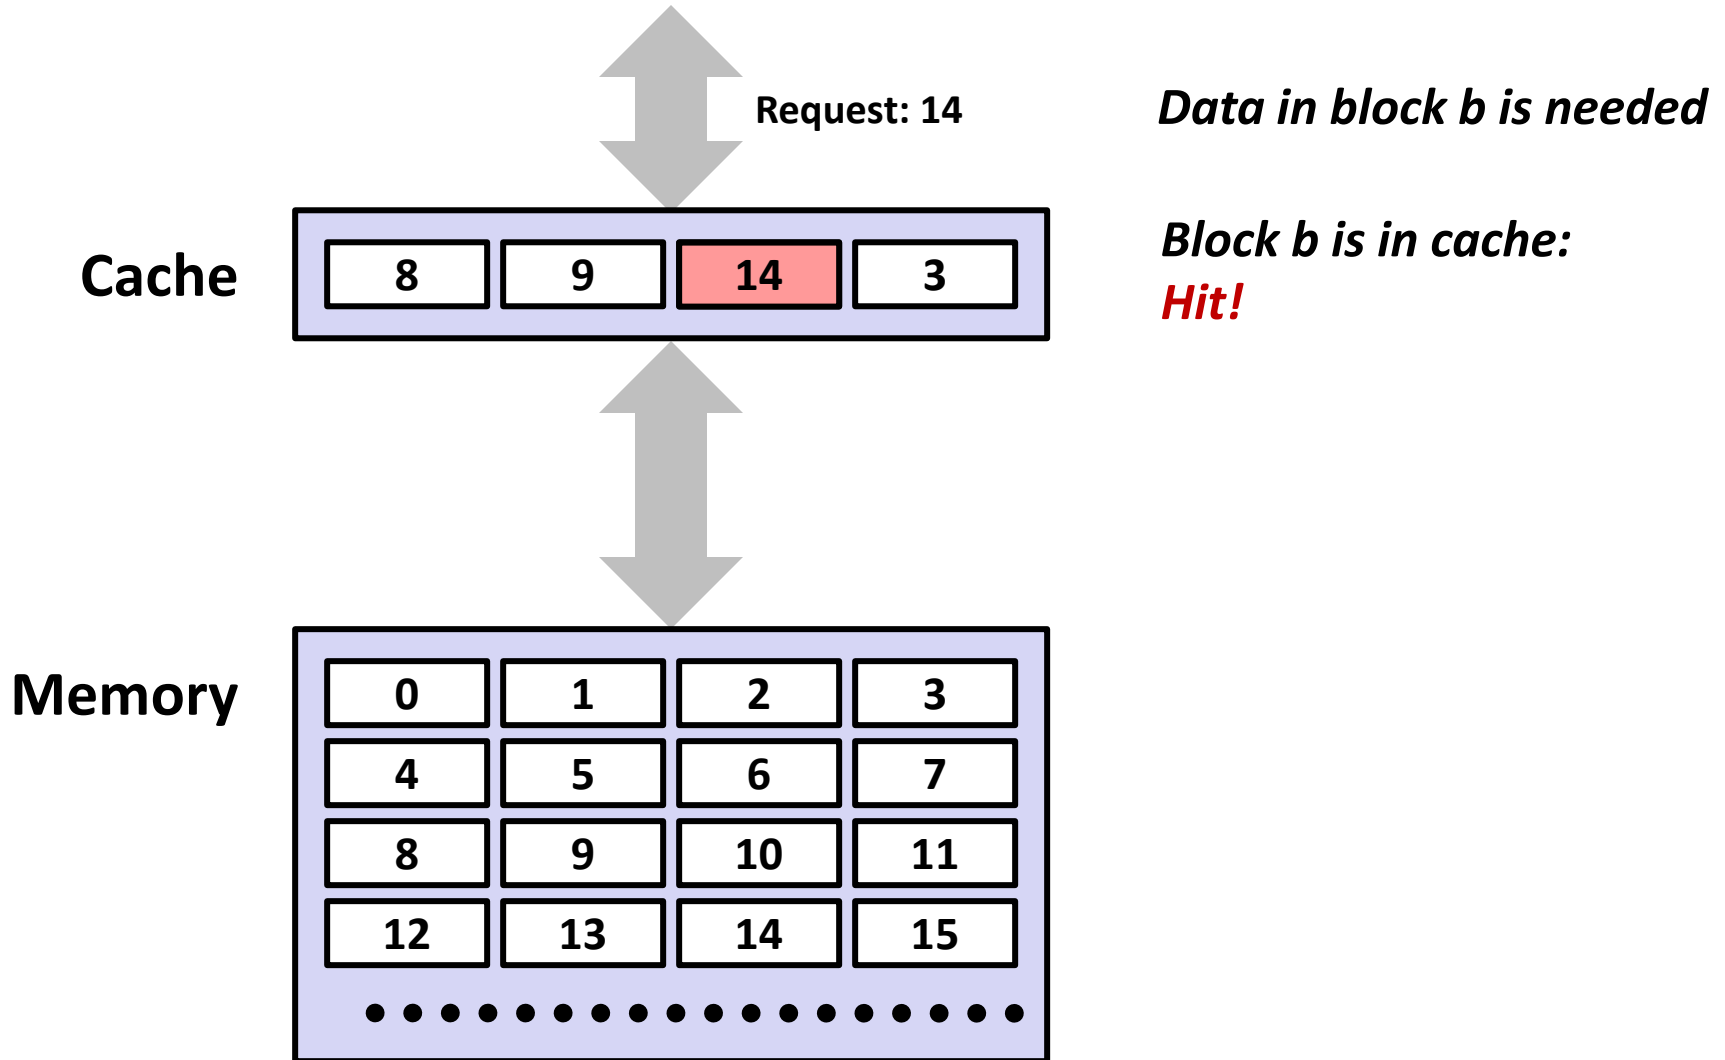

# Caches

- **Cache:** A smaller, faster storage device that acts as a staging area for a subset of the data in a larger, slower device.
- **Fundamental idea of a memory hierarchy:**
  - For each  $k$ , the faster, smaller device at level  $k$  serves as a cache for the larger, slower device at level  $k+1$ .
- **Why do memory hierarchies work?**
  - Because of locality, programs tend to access the data at level  $k$  more often than they access the data at level  $k+1$ .
  - Thus, the storage at level  $k+1$  can be slower, and thus larger and cheaper per bit.
- **Big Idea (Ideal):** The memory hierarchy creates a large pool of storage that costs as much as the cheap storage near the bottom, but that serves data to programs at the rate of the fast storage near the top.

# General Cache Concepts

# General Cache Concepts: Hit

# General Cache Concepts: Miss

*Data in block b is needed*

*Block b is not in cache:  
**Miss!***

*Block b is fetched from  
memory*

*Block b is stored in cache*

- **Placement policy:**  
determines where b goes
- **Replacement policy:**  
determines which block  
gets evicted (victim)

**Impact of spatial locality  
on number of misses?**

# General Caching Concepts:

## 3 Types of Cache Misses

### ■ Cold (compulsory) miss

- Cold misses occur because the cache starts empty and this is the first reference to the block.

### ■ Capacity miss

- Occurs when the set of active cache blocks (**working set**) is larger than the cache.

### ■ Conflict miss

- Most caches limit blocks at level  $k+1$  to a small subset (sometimes a singleton) of the block positions at level  $k$ .
  - E.g. Block  $i$  at level  $k+1$  must be placed in block  $(i \bmod 4)$  at level  $k$ .
- Conflict misses occur when the level  $k$  cache is large enough, but multiple data objects all map to the same level  $k$  block.
  - E.g. Referencing blocks 0, 8, 0, 8, 0, 8, ... would miss every time.

# Examples of Caching in the Mem. Hierarchy

Cache Type	What is Cached?	Where is it Cached?	Latency (cycles)	Managed By
Registers	4-8 byte words	CPU core	0	Compiler
TLB	Address translations	On-Chip TLB	0	Hardware MMU
L1 cache	64-byte blocks	On-Chip L1	4	Hardware
L2 cache	64-byte blocks	On-Chip L2	10	Hardware
Virtual Memory	4-KB pages	Main memory	100	Hardware + OS
Buffer cache	Parts of files	Main memory	100	OS
Disk cache	Disk sectors	Disk controller	100,000	Disk firmware
Network buffer cache	Parts of files	Local disk	10,000,000	NFS client
Browser cache	Web pages	Local disk	10,000,000	Web browser
Web cache	Web pages	Remote server disks	1,000,000,000	Web proxy server

Canvas > Day 9 – Memory Hierarchy

# Today

- The memory abstraction
- RAM : main memory building block
- Locality of reference
- The memory hierarchy
- **Storage technologies and trends**

# Storage Technologies

## ■ Magnetic Disks

- Store on magnetic medium
- Electromechanical access

## ■ Nonvolatile (Flash) Memory

Close-up image of V-NAND flash array

chipworks

- Store as persistent charge
- Implemented with 3-D structure
  - 100+ levels of cells
  - 3 bits data per cell

# What's Inside A Disk Drive?

*Image courtesy of Seagate Technology*

# Disk Geometry

- Disks consist of **platters**, each with two **surfaces**.
- Each surface consists of concentric rings called **tracks**.
- Each track consists of **sectors** separated by **gaps**.

# Disk Capacity

- **Capacity:** maximum number of bits that can be stored.
  - Vendors express capacity in units of gigabytes (GB) or terabytes (TB), where  $1 \text{ GB} = 10^9 \text{ Bytes}$  and  $1 \text{ TB} = 10^{12} \text{ Bytes}$
- **Capacity is determined by these technology factors:**
  - **Recording density** (bits/in): number of bits that can be squeezed into a 1 inch segment of a track.
  - **Track density** (tracks/in): number of tracks that can be squeezed into a 1 inch radial segment.
  - **Areal density** (bits/in<sup>2</sup>): product of recording and track density.

# Disk Operation (Single-Platter View)

The disk surface spins at a fixed rotational rate

The read/write *head* is attached to the end of the *arm* and flies over the disk surface on a thin cushion of air.

By moving radially, the arm can position the read/write head over any track.

# Disk Operation (Multi-Platter View)

# Disk Access – Service Time Components

# Disk Access Time

## ■ Average time to access some target sector approximated by:

$$T_{\text{access}} = T_{\text{avg seek}} + T_{\text{avg rotation}} + T_{\text{avg transfer}}$$

## ■ Seek time ( $T_{\text{avg seek}}$ )

- Time to position heads over cylinder containing target sector.
- Typical  $T_{\text{avg seek}}$  is 3—9 ms

## ■ Rotational latency ( $T_{\text{avg rotation}}$ )

- Time waiting for first bit of target sector to pass under r/w head.
- $T_{\text{avg rotation}} = 1/2 \times 1/\text{RPMs} \times 60 \text{ sec}/1 \text{ min}$
- Typical rotational rate = 7,200 RPMs

## ■ Transfer time ( $T_{\text{avg transfer}}$ )

- Time to read the bits in the target sector.
- $T_{\text{avg transfer}} = 1/\text{RPM} \times 1/(\text{avg \# sectors/track}) \times 60 \text{ secs}/1 \text{ min}$

time for one rotation (in minutes)      fraction of a rotation to be read

# Disk Access Time Example

## ■ Given:

- Rotational rate = 7,200 RPM
- Average seek time = 9 ms
- Avg # sectors/track = 400

## ■ Derived:

- $T_{\text{avg rotation}} = 1/2 \times (60 \text{ secs}/7200 \text{ RPM}) \times 1000 \text{ ms/sec} = 4 \text{ ms}$
- $T_{\text{avg transfer}} = 60/7200 \times 1/400 \times 1000 \text{ ms/sec} = 0.02 \text{ ms}$
- $T_{\text{access}} = 9 \text{ ms} + 4 \text{ ms} + 0.02 \text{ ms}$

## ■ Important points:

- Access time dominated by seek time and rotational latency.
- First bit in a sector is the most expensive, the rest are free.
- *SRAM access time is about 4 ns/doubleword, DRAM about 60 ns*
  - *Disk is about 40,000 times slower than SRAM,*
  - *2,500 times slower than DRAM.*

# I/O Bus

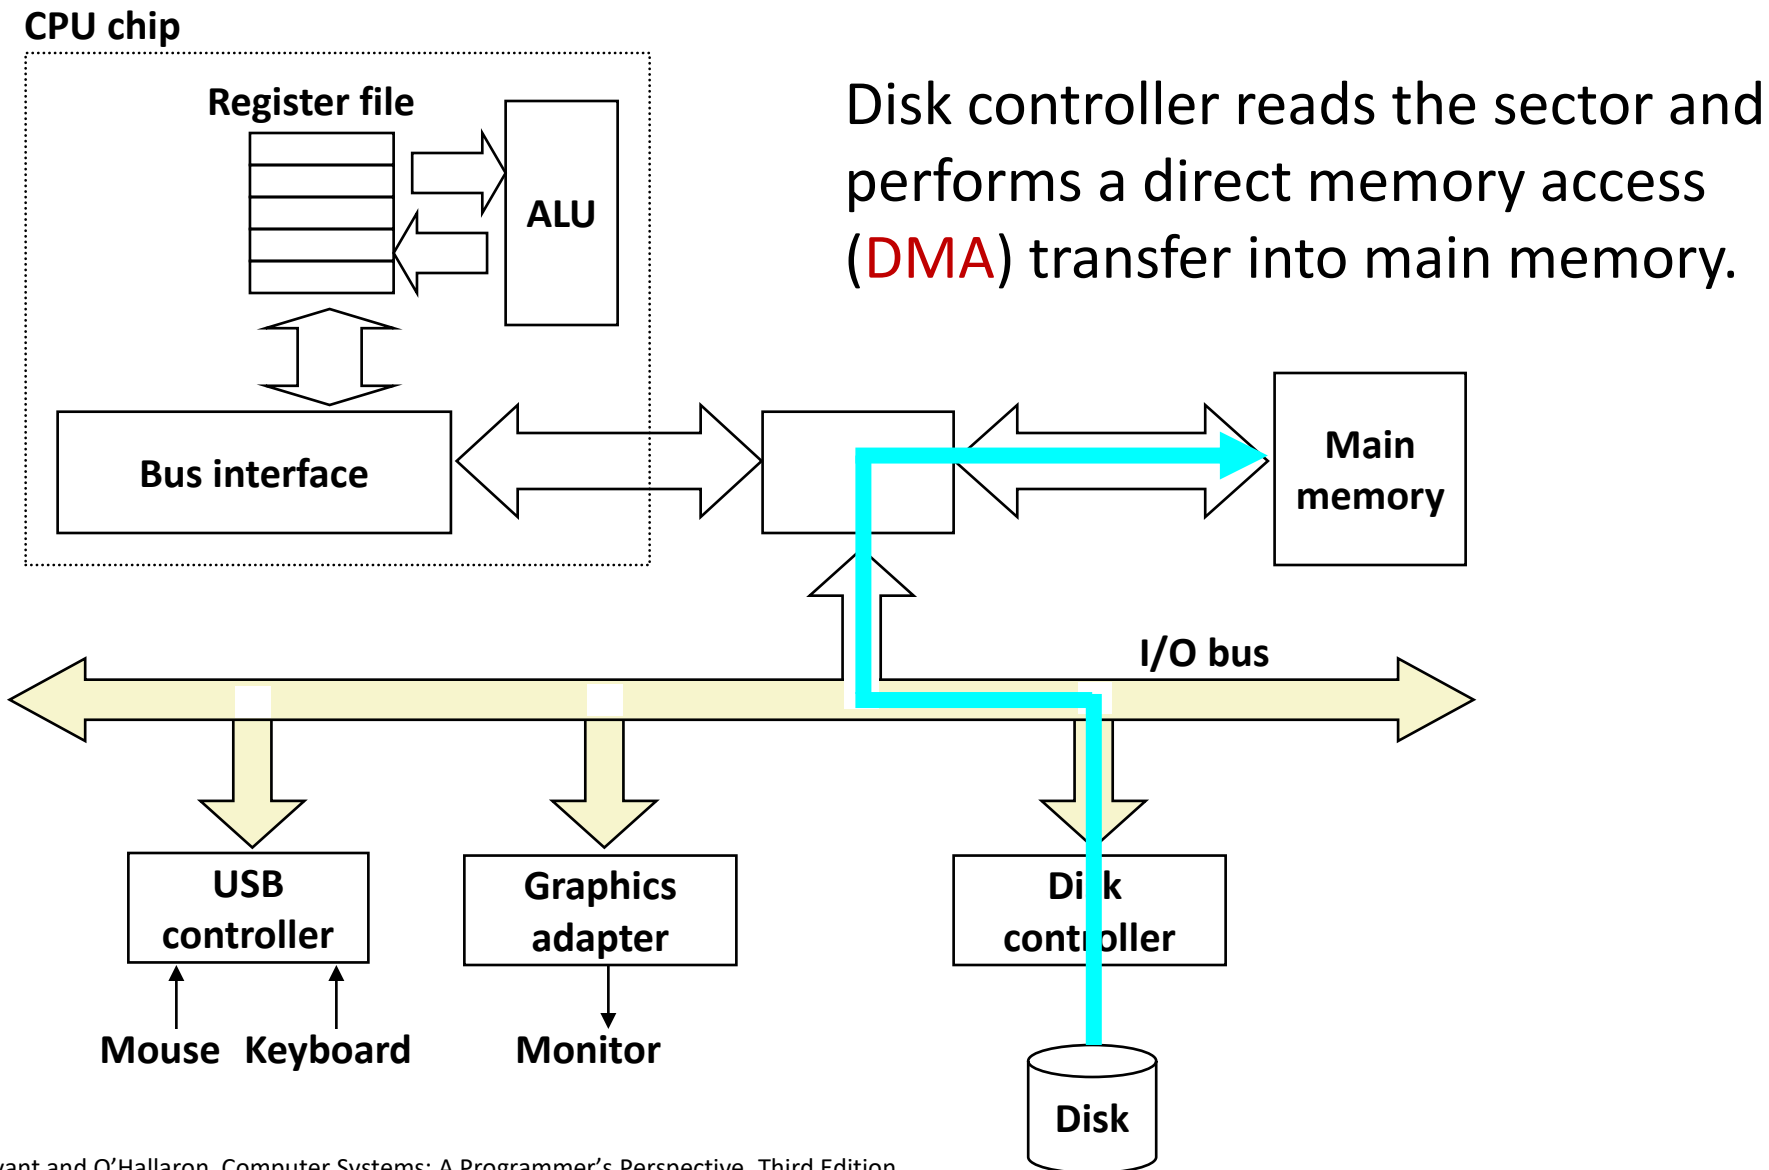

# Reading a Disk Sector (1)

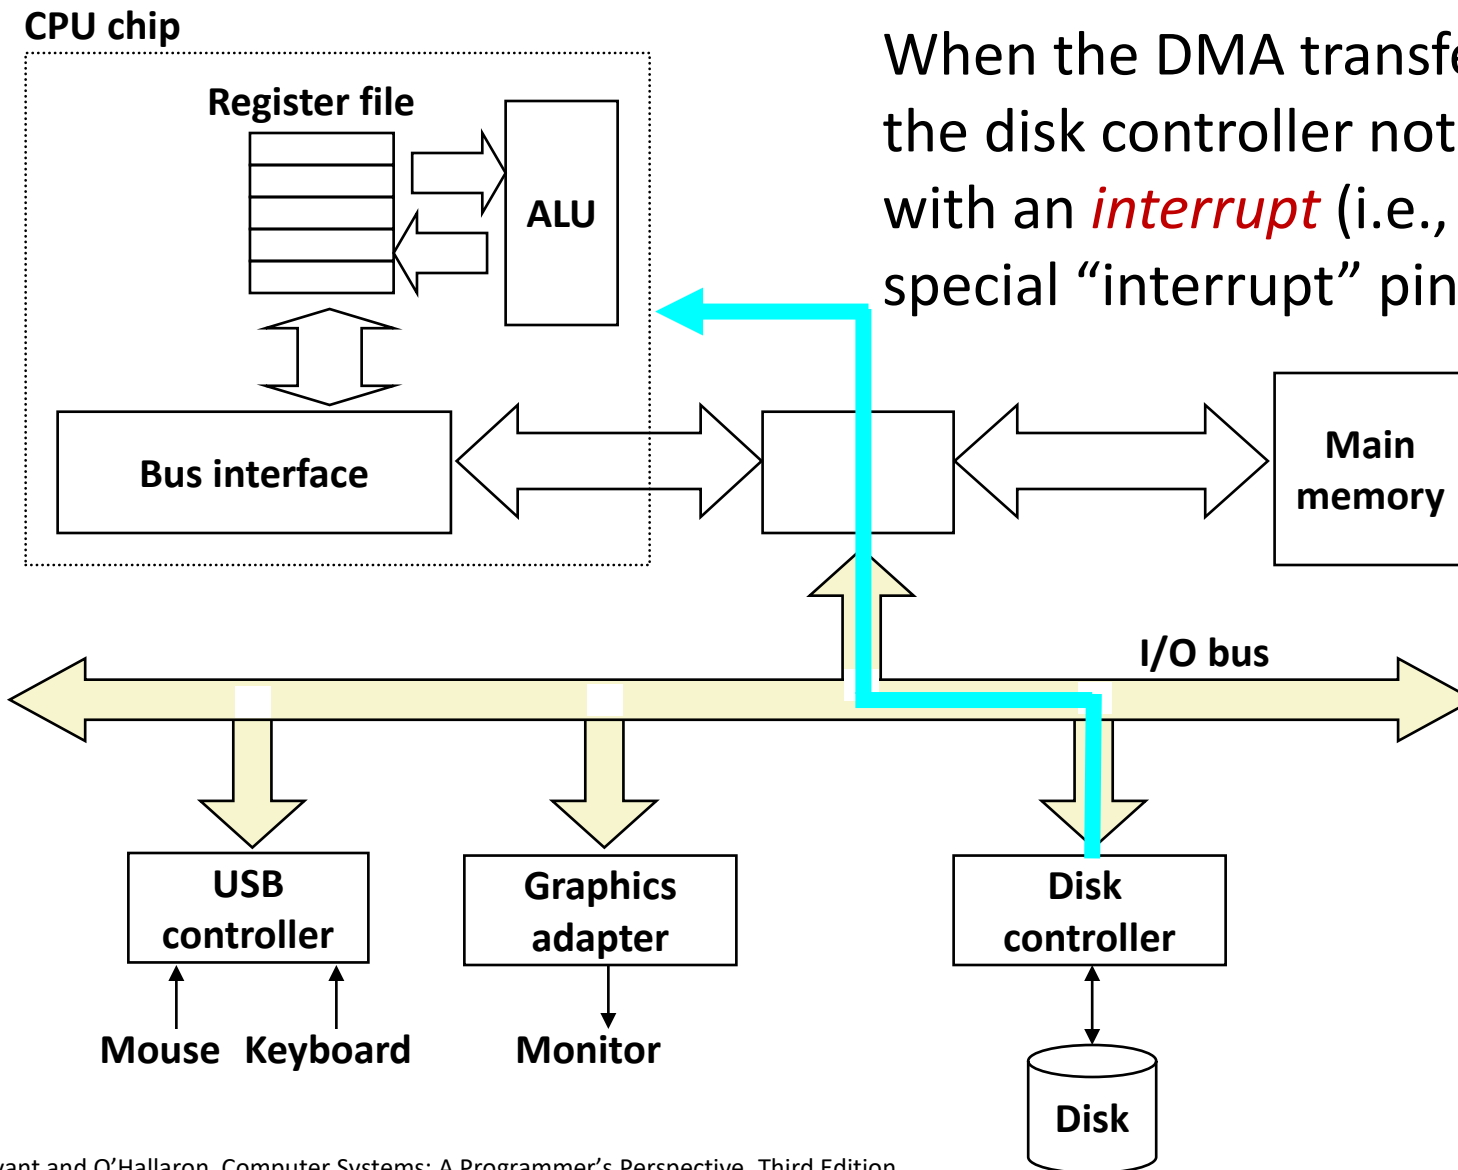

CPU initiates a disk read by writing a command, logical block number, and destination memory address to a **port** (address) associated with disk controller.

# Reading a Disk Sector (2)

# Reading a Disk Sector (3)

# Nonvolatile Memories

## ■ DRAM and SRAM are volatile memories

- Lose information if powered off.

## ■ Nonvolatile memories retain value even if powered off

- Read-only memory (**ROM**): programmed during production
- Electrically erasable PROM (**EEPROM**): electronic erase capability
- Flash memory: EEPROMs, with partial (block-level) erase capability
  - Wears out after about 100,000 erasings
- 3D XPoint (Intel Optane) & emerging NVMs
  - New materials

## ■ Uses for Nonvolatile Memories

- Firmware programs stored in a ROM (BIOS, controllers for disks, network cards, graphics accelerators, security subsystems,...)
- Solid state disks (replacing rotating disks)
- Disk caches

# Solid State Disks (SSDs)

- **Pages: 512KB to 4KB, Blocks: 32 to 128 pages**
- **Data read/written in units of pages.**
- **Page can be written only after its block has been erased.**
- **A block wears out after about 100,000 repeated writes.**

# SSD Performance Characteristics

## ■ Benchmark of Samsung 940 EVO Plus

<https://ssd.userbenchmark.com/SpeedTest/711305/Samsung-SSD-970-EVO-Plus-250GB>

Sequential read throughput	2,126 MB/s	Sequential write tput	1,880 MB/s
Random read throughput	140 MB/s	Random write tput	59 MB/s

## ■ Sequential access faster than random access

- Common theme in the memory hierarchy

## ■ Random writes are somewhat slower

- Erasing a block takes a long time (~1 ms).
- Modifying a block page requires all other pages to be copied to new block.
- Flash translation layer allows accumulating series of small writes before doing block write.

# SSD Tradeoffs vs Rotating Disks

## ■ Advantages

- No moving parts → faster, less power, more rugged

## ■ Disadvantages

- Have the potential to wear out
  - Mitigated by “wear leveling logic” in flash translation layer
  - E.g. Samsung 940 EVO Plus guarantees 600 writes/byte of writes before they wear out
  - Controller migrates data to minimize wear level
- In 2019, about 4 times more expensive per byte
  - And, relative cost will keep dropping

## ■ Applications

- Smartphones, laptops
- Increasingly common in desktops and servers

# Summary

- **The speed gap between CPU, memory and mass storage continues to widen.**
- **Well-written programs exhibit a property called *locality*.**
- **Memory hierarchies based on *caching* close the gap by exploiting locality.**
- **Flash memory progress outpacing all other memory and storage technologies (DRAM, SRAM, magnetic disk)**
  - Able to stack cells in three dimensions
