The Graphics Pipeline, Revisited

- Must eliminate objects outside viewing frustum
- Tied in with projections
 - **Clipping**: object space (eye coordinates)
 - **Scissoring**: image space (pixels in frame buffer)
- Introduce **clipping** in stages
 - 2D (for simplicity)
 - 3D (as in OpenGL)
- In a later lecture: **scissoring**

Transformations and Projections

- Sequence applied in many implementations
 1. Object coordinates to
 2. Eye coordinates to
 3. Clip coordinates to
 4. Normalized device coordinates to
 5. Screen coordinates

Clipping Against a Frustum

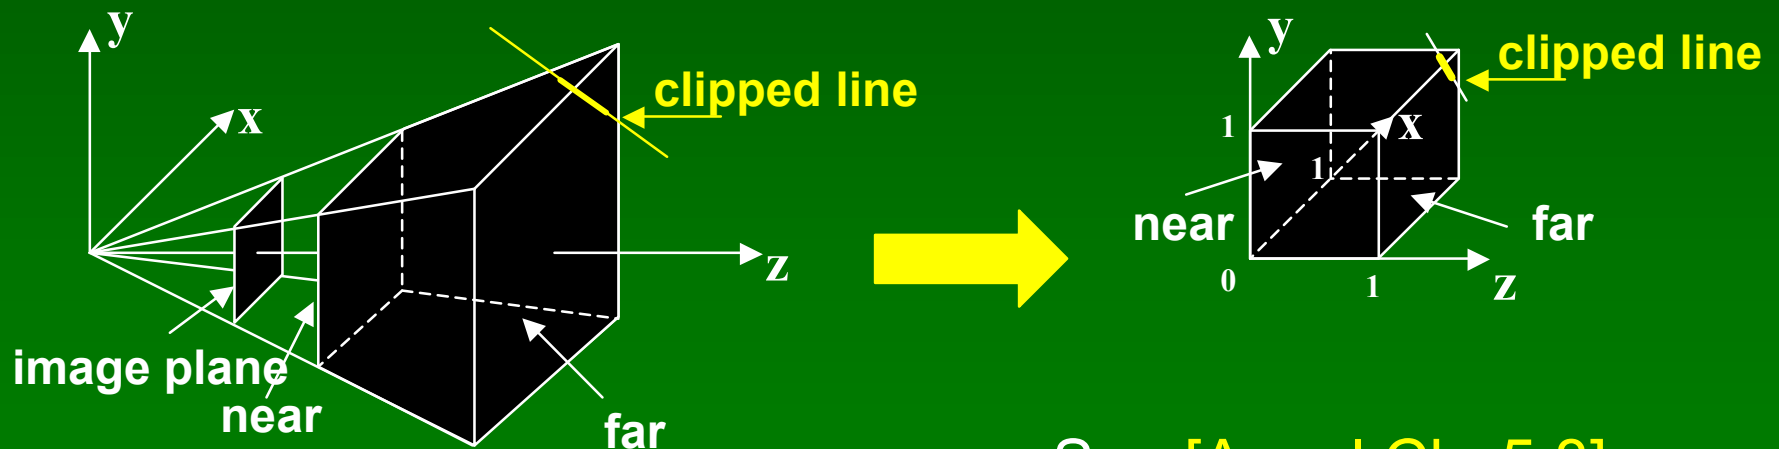

- General case of frustum (truncated pyramid)

- Clipping is tricky because of frustum shape

Perspective Normalization

- Solution:
 - Implement perspective projection by **perspective normalization** and orthographic projection
 - Perspective normalization is a homogeneous tfm.

See [Angel Ch. 5.8]

The Normalized Frustum

- OpenGL uses $-1 \leq x, y, z \leq 1$ (others possible)
- Clip against resulting cube
- Clipping against programmer-specified planes is different and more expensive
- Often a useful programming device

The Viewport Transformation

- Transformation sequence again:
 1. **Camera**: From object coordinates to eye coords
 2. **Perspective normalization**: to clip coordinates
 3. **Clipping**
 4. **Perspective division**: to normalized device coords.
 5. **Orthographic projection** (setting $z_p = 0$)
 6. **Viewport transformation**: to screen coordinates
- Viewport transformation can distort
- Often in OpenGL: resize callback

Line-Segment Clipping

- General: 3D object against cube
- Simpler case:
 - In 2D: line against square or rectangle
 - Before scan conversion (rasterization)
 - Later: polygon clipping
- Several practical algorithms
 - Avoid expensive line-rectangle intersections
 - Cohen-Sutherland Clipping
 - Liang-Barsky Clipping
 - Many more [see Foley et al.]

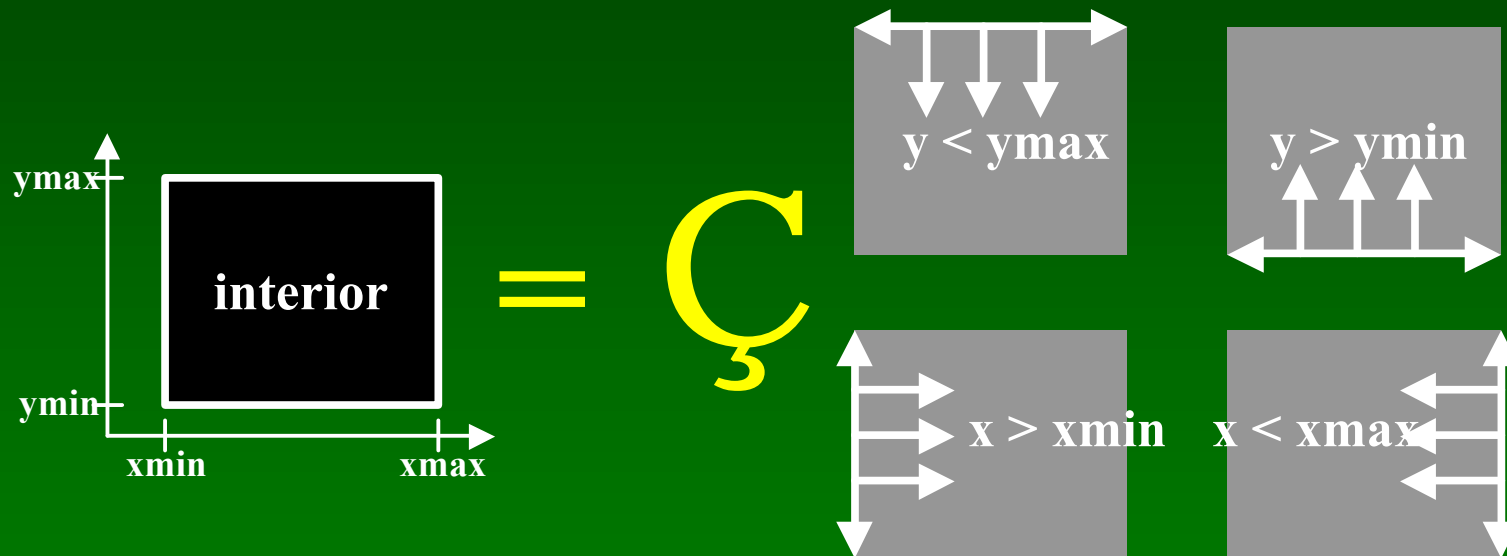

Clipping Against Rectangle

- **Line-segment clipping**: modify endpoints of lines to lie within clipping rectangle
- Could calculate intersections of line (segments) with clipping rectangle (expensive)

Cohen-Sutherland Clipping

- Clipping rectangle as intersection of 4 half-planes

- Encode results of four half-plane tests
- Generalizes to 3 dimensions (6 half-planes)

Outcodes

- Divide space into 9 regions
- 4-bit **outcode** determined by comparisons

- $o_1 = \text{outcode}(x_1, y_1)$ and $o_2 = \text{outcode}(x_2, y_2)$

Cases for Outcodes

- Outcomes: accept, reject, subdivide

- $o_1 = o_2 = 0000$: accept
- $o_1 \& o_2 \neq 0000$: reject
- $o_1 = 0000, o_2 \neq 0000$: subdiv
- $o_1 \neq 0000, o_2 = 0000$: subdiv
- $o_1 \& o_2 = 0000$: subdiv

Cohen-Sutherland Subdivision

- Pick outside endpoint ($o \neq 0000$)
- Pick a crossed edge ($o = b_0b_1b_2b_3$ and $b_k \neq 0$)
- Compute intersection of this line and this edge
- Replace endpoint with intersection point
- Restart with new line segment
 - Outcodes of second point are unchanged
- Must converge (roundoff errors?)

Liang-Barsky Clipping

- Starting point is parametric form

$$p(\alpha) = (1 - \alpha)p_1 + \alpha p_2, \quad 0 \leq \alpha \leq 1$$

$$x(\alpha) = (1 - \alpha)x_1 + \alpha x_2$$

$$y(\alpha) = (1 - \alpha)y_1 + \alpha y_2$$

- Compute four intersections with extended clipping rectangle
- Will see that this can be avoided

Ordering of intersection points

- Order the intersection points
- Figure (a): $1 > \alpha_4 > \alpha_3 > \alpha_2 > \alpha_1 > 0$
- Figure (b): $1 > \alpha_4 > \alpha_2 > \alpha_3 > \alpha_1 > 0$

Liang-Barsky Efficiency Improvements

- Efficiency improvement 1:
 - Compute intersections one by one
 - Often can reject before all four are computed
- Efficiency improvement 2:
 - Equations for α_3, α_2

$$y_{max} = (1 - \alpha_3)y_1 + \alpha_3y_2$$

$$x_{min} = (1 - \alpha_2)x_1 + \alpha_2x_2$$

$$\alpha_3 = \frac{y_{max} - y_1}{y_2 - y_1} \quad \alpha_2 = \frac{x_{min} - x_1}{x_2 - x_1}$$

- Compare α_3, α_2 without floating-point division

Line-Segment Clipping Assessment

- Cohen-Sutherland
 - Works well if many lines can be rejected early
 - Recursive structure (multiple subdiv) a drawback
- Liang-Barsky
 - Avoids recursive calls (multiple subdiv)
 - Many cases to consider (tedious, but not expensive)
 - Used more often in practice (?)

Outline

- Line-Segment Clipping
 - Cohen-Sutherland
 - Liang-Barsky
- Polygon Clipping
 - Sutherland-Hodgeman
- Clipping in Three Dimensions

Polygon Clipping

- Convert a polygon into **one or more** polygons
- Their union is intersection with clip window
- Alternatively, we can first tessellate concave polygons (OpenGL supported)

Concave Polygons

- Approach 1: clip and join to a single polygon

- Approach 2: tessellate and clip triangles

Sutherland-Hodgeman I

- Subproblem:
 - Input: polygon (vertex list) and single clip plane
 - Output: new (clipped) polygon (vertex list)
- Apply once for each clip plane
 - 4 in two dimensions
 - 6 in three dimensions
 - Can arrange in pipeline

Sutherland-Hodgeman II

- To clip vertex list (polygon) against half-plane:
 - Test first vertex. Output if inside, otherwise skip.
 - Then loop through list, testing transitions
 - In-to-in: output vertex
 - In-to-out: output intersection
 - out-to-in: output intersection and vertex
 - out-to-out: no output
 - Will output clipped polygon as vertex list
- May need some cleanup in concave case
- Can combine with Liang-Barsky idea

Other Cases and Optimizations

- Curves and surfaces
 - Analytically if possible
 - Through approximating lines and polygons otherwise
- Bounding boxes
 - Easy to calculate and maintain
 - Sometimes big savings

Outline

- Line-Segment Clipping
 - Cohen-Sutherland
 - Liang-Barsky
- Polygon Clipping
 - Sutherland-Hodgeman
- Clipping in Three Dimensions

Clipping Against Cube

- Derived from earlier algorithms
- Can allow right parallelepiped

Cohen-Sutherland in 3D

- Use 6 bits in outcode
 - $b_4: z > z_{\max}$
 - $b_5: z < z_{\min}$
- Other calculations as before

Liang-Barsky in 3D

- Add equation $z(\alpha) = (1 - \alpha) z_1 + \alpha z_2$
- Solve, for p_0 in plane and normal n :

$$p(\alpha) = (1 - \alpha)p_1 + \alpha p_2$$
$$n \cdot (p(\alpha) - p_0) = 0$$

- Yields

$$\alpha = \frac{n \cdot (p_0 - p_1)}{n \cdot (p_2 - p_1)}$$

- Optimizations as for Liang-Barsky in 2D

Perspective Normalization

- Intersection simplifies for orthographic viewing
 - One division only (no multiplication)
 - Other Liang-Barsky optimizations also apply
- Otherwise, use perspective normalization
 - Reduces to orthographic case
 - Applies to oblique and perspective viewing

Normalization of oblique projections

Summary: Clipping

- Clipping line segments to rectangle or cube
 - Avoid expensive multiplications and divisions
 - Cohen-Sutherland or Liang-Barsky
- Clipping to viewing frustum
 - Perspective normalization to orthographic projection
 - Apply clipping to cube from above
- Client-specific clipping
 - Use more general, more expensive form
- Polygon clipping
 - Sutherland-Hodgeman pipeline

Preview and Announcements

- Scan conversion
- Anti-aliasing
- Other pixel-level operations
- **Assignment 5 due a week from Thursday!**
- **Start early!**
- Sriram's office hours now Mon 4:30-6:30
- Movie
- Returning Midterm
