

## UNIT 13A

### AI: Game Trees & Search Strategies

15110 Principles of Computing, Carnegie Mellon University - CORTINA

1

## Artificial Intelligence

- Branch of computer science that studies the use of computers to perform computational processes normally associated with human intellect and skill.
- Some areas of AI:
  - Expert systems      Knowledge representation      Robotics
  - Machine learning      Natural language processing
- Allen Newell and Herbert Simon (CMU)
  - General Problem Solver (GPS) in 1957
  - Awarded the Turing Award in 1975 for "basic contributions to artificial intelligence, the psychology of human cognition, and list processing."

Newell

Simon

2

## Game Trees

- For most games, the number of possible moves and potential outcomes is HUGE.
- A classical AI technique used to manage this computation is the use of a game tree.
  - A tree is built with a root node representing the current state of the game.
  - Children nodes are generated representing the state of the game for each possible move.
  - The tree is propagated down, building more children nodes for moves allowed by the next move, etc.
  - Leaves are terminal states of the game.

3

## Tic Tac Toe

15110 Principles of Computing, Carnegie Mellon University - CORTINA

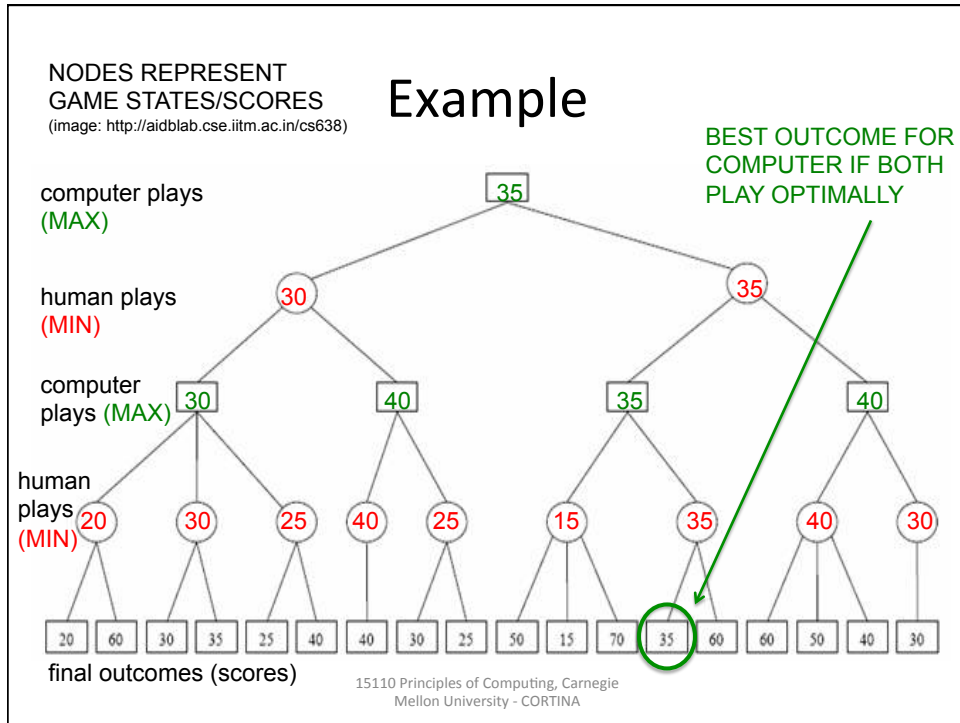

4

## Game Trees are BIG!

- Assuming that all nine positions must be filled before the game ends, how big does this tree get?
- Of course, in real Tic-Tac-Toe, a player can win without filling the whole board.
  - What is the first level of the tree where this can occur?
  - How big is this tree up to this level?

## Minimax Algorithm

- Computer wants to maximize its score.  
Human wants to minimize computer's score.  
What move should computer make given final outcomes?
- Given final outcomes ranked as a "score", work up the tree. At the next level up, if the computer is playing, store the max of each of its children. If the human is playing, store the min of each of its children.
- Once you get to the root, the value there will indicate the optimal move to make.

## Dealing with the Huge Search Space

- How does a computer program that plays tic-tac-toe, or chess, deal with the huge size of the game trees that can be generated?
  - In chess, the average number of possible next moves is around 35, and the average number of moves in a chess game is around 100, so the number of possibilities a computer must check is about  $35^{100}$ , which is beyond hope, even for our fastest computers!
- These programs use heuristics to narrow the search space in the tree that must be examined

## Heuristics

- Since it is believed that human thought is not entirely algorithmic, many problems in AI are solved by using heuristics.
- A heuristic is an algorithm that typically finds a reasonably good solution to a problem (rather than the optimal, best solution) in order to reduce the running time to a reasonable amount.

## AI Opponents

- Consider the game of Pentecost.
  - Players alternate, placing their stones on the game board at the intersection of lines, one at a time.
  - The object of the game is to be the first player to either get five stones in a straight line or capture 5 pairs of stones of the other player.
  - If we were write a computer program to play Pentecost against a human player, how does the computer calculate its moves when there are a huge amount of possibilities to consider?

## Heuristics

- We can use heuristics to make the problem easier to deal with.
  - Check for x-pieces in a row.
  - Check for capture possibilities.
  - Check for x-pieces in a row for opponent.
  - Check for opponents potential to make a capture.

1
2
3

**Example:**  
Code each cell based on number of opponent pieces in same row, column and diagonal.

11

## “Deep Blue”

- IBM's "Deep Blue" computer beats Gary Kasparov in a chess match in 1997.
- Heuristics values:
  - The value of each piece. (1 for pawn up to 9 for queen)
  - The amount of control each side has over the board.
  - The safety of the king.
  - The quickness that pieces move into fighting position.

12

## “Chinook”

- Created by computer scientists from the University of Alberta to play checkers (draughts) in 1989.
- In 2007, the team led by Jonathan Schaeffer announced that Chinook could never lose a game.
- Chinook's algorithms featured:
  - a library of opening moves from games played by grandmasters
  - a deep search algorithm
  - a good move evaluation function (based on piece count, kings count, trapped kings, player's turn, “runaway checkers”, etc.)
  - an end-game database for all positions with eight pieces or fewer. and other minor factors.
- Is Chinook intelligent?

15110 Principles of Computing, Carnegie Mellon University - CORTINA

13

## “Watson”

- IBM's “Watson” computer beats champions Ken Jennings and Brad Rutter in a 2-game match on Jeopardy! in 2011.
- Watson parsed clues into different keywords and fragments.
- Watson had 4TB of data content but was not connected to the Internet during the game.
- Watson executed 1000s of proven language analysis algorithms concurrently. The more algorithms that pointed to the same answer, the more confident Watson was and the more likely it would buzz in.
- Is Watson intelligent?
