Review: Dynamic Memory Allocation

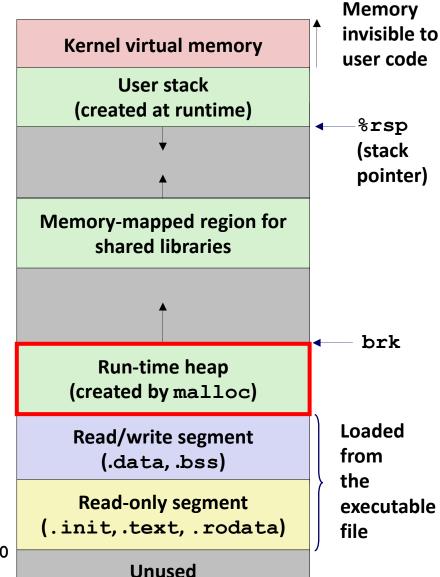

Application

Dynamic Memory Allocator

Heap

- Programmers use dynamic memory allocators (such as malloc) to acquire virtual memory (VM) at run time.
 - for data structures whose size is only known at runtime
- Dynamic memory allocators manage an area of process
 VM known as the heap.

0x400000

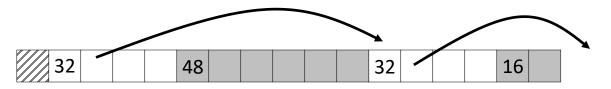

Review: Keeping Track of Free Blocks

Method 1: Implicit list using length—links all blocks

Need to tag each block as allocated/free

Method 2: Explicit list among the free blocks using pointers

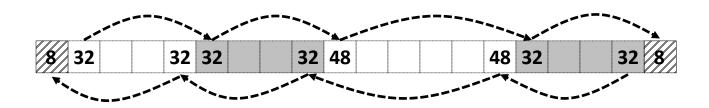

Need space for pointers

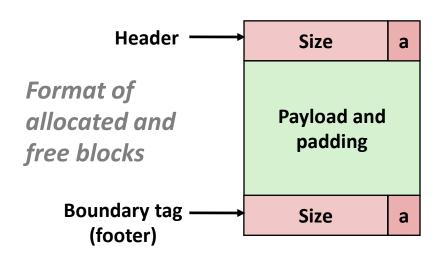

- Method 3: Segregated free list
 - Different free lists for different size classes
- Method 4: *Blocks sorted by size*
 - Can use a balanced tree (e.g. Red-Black tree) with pointers within each free block, and the length used as a key

Review: Boundary Tags for Coalescing

Boundary tags

- Replicate size/allocated word at "bottom" (end) of free blocks
- Allows us to traverse the "list" backwards, but requires extra space
- Important and general technique!

a = 1: Allocated block

a = 0: Free block

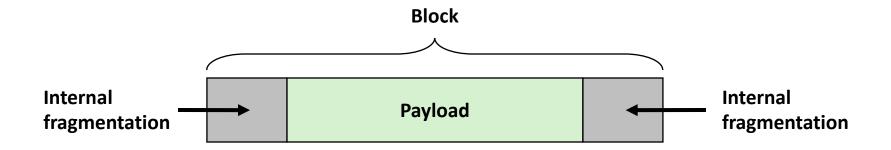

Size: Total block size

Payload: Application data (allocated blocks only)

Disadvantage: Internal fragmentation

Review: Internal vs. External Fragmentation

 For a given block, internal fragmentation occurs if payload is smaller than block size

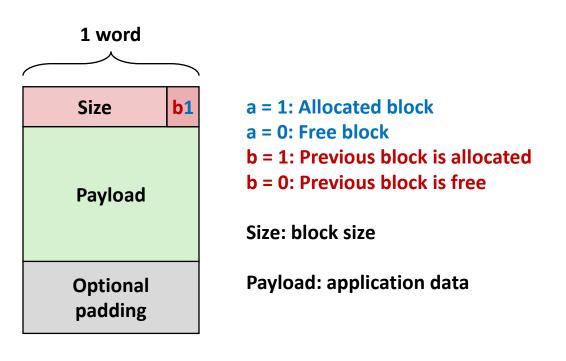

■ External fragmentation occurs when there is enough aggregate heap memory, but no single free block is large enough

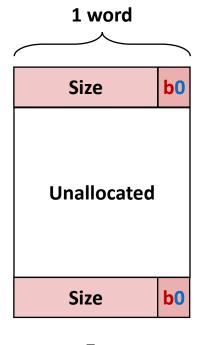

Review: No Boundary Tag for Allocated Blocks

- Boundary tag needed only for free blocks
- When sizes are multiples of 16, have 4 spare bits

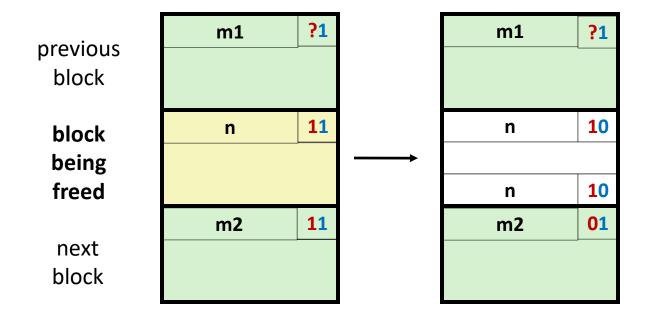

Allocated Block

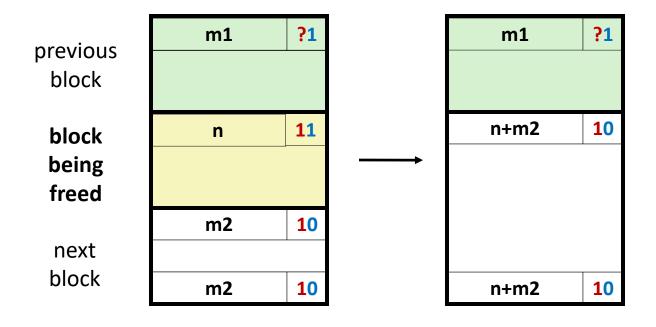

Free Block

No Boundary Tag for Allocated Blocks (Case 1)

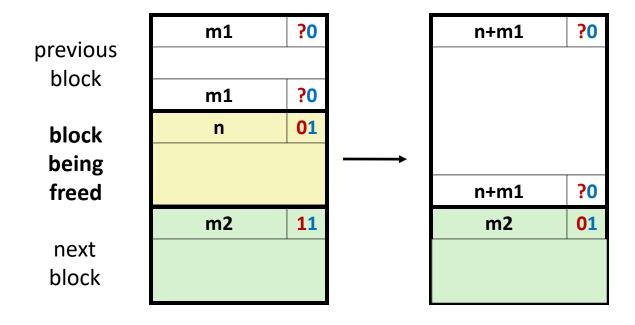

Header: Use 2 bits (address bits always zero due to alignment):

No Boundary Tag for Allocated Blocks (Case 2)

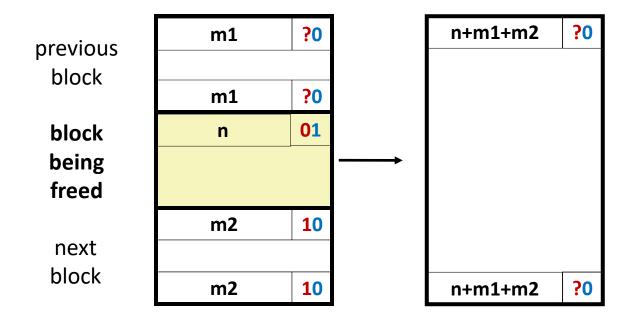

Header: Use 2 bits (address bits always zero due to alignment):

No Boundary Tag for Allocated Blocks (Case 3)

Header: Use 2 bits (address bits always zero due to alignment):

No Boundary Tag for Allocated Blocks (Case 4)

Header: Use 2 bits (address bits always zero due to alignment):

Implicit Lists Summary

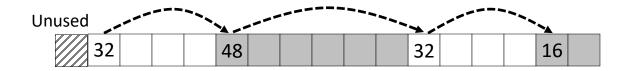

- Implementation: very simple
- Allocate cost:
 - linear time worst case
- Free cost:
 - constant time worst case
 - even with coalescing
- Memory Overhead:
 - Depends on placement policy
 - Strategies include first fit, next fit, and best fit
- Not used in practice for malloc/free because of lineartime allocation
 - used in many special purpose applications
- However, the concepts of splitting and boundary tag coalescing are general to all allocators

Today

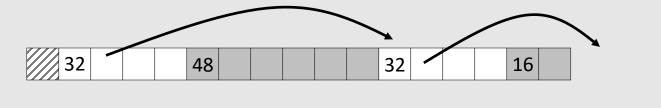

- Implicit free lists (review)
- Explicit free lists CSAPP 9.9.13
- Segregated free lists
 CSAPP 9.9.14
- Memory-related perils and pitfalls CSAPP 9.11

Keeping Track of Free Blocks

Method 1: Implicit list using length—links all blocks

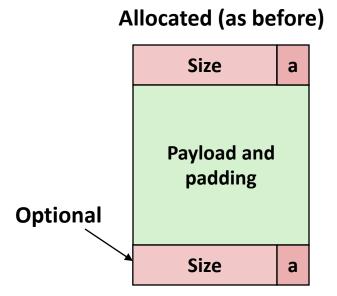

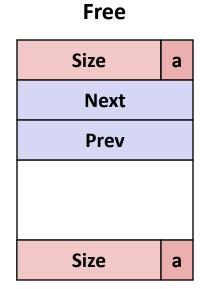

Method 2: Explicit list among the free blocks using pointers

- Method 3: Segregated free list
 - Different free lists for different size classes
- Method 4: *Blocks sorted by size*
 - Can use a balanced tree (e.g. Red-Black tree) with pointers within each free block, and the length used as a key

Explicit Free Lists

Maintain list(s) of free blocks, not all blocks

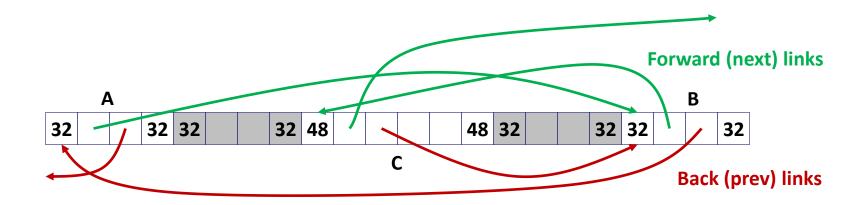

- Luckily we track only free blocks, so we can use payload area
- The "next" free block could be anywhere
 - So we need to store forward/back pointers, not just sizes
- Still need boundary tags for coalescing
 - To find adjacent blocks according to memory order

Explicit Free Lists

Logically:

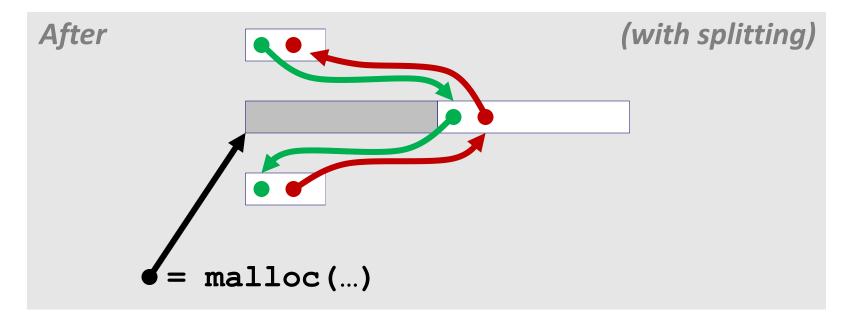

Physically: blocks can be in any order

Allocating From Explicit Free Lists

conceptual graphic

Freeing With Explicit Free Lists

Insertion policy: Where in the free list do you put a newly freed block?

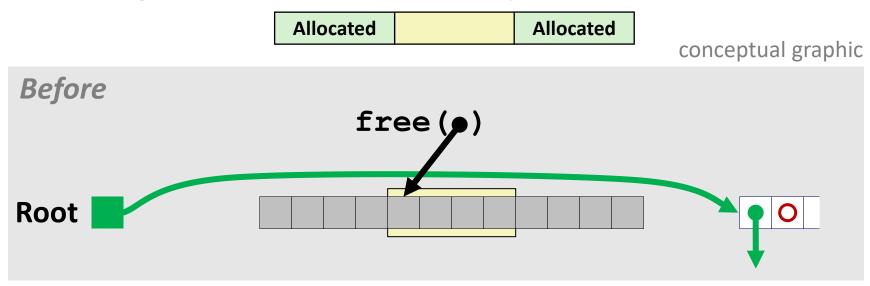

Unordered

- LIFO (last-in-first-out) policy
 - Insert freed block at the beginning of the free list
- FIFO (first-in-first-out) policy
 - Insert freed block at the end of the free list
- Pro: simple and constant time
- Con: studies suggest fragmentation is worse than address ordered

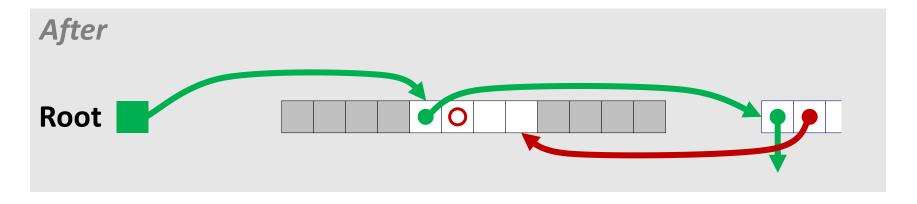

Address-ordered policy

- Insert freed blocks so that free list blocks are always in address order:
 addr(prev) < addr(curr) < addr(next)</p>
- Con: requires search
- Pro: studies suggest fragmentation is lower than LIFO/FIFO

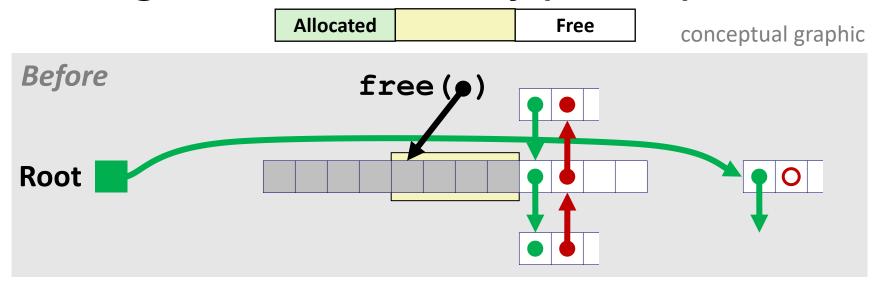

Freeing With a LIFO Policy (Case 1)

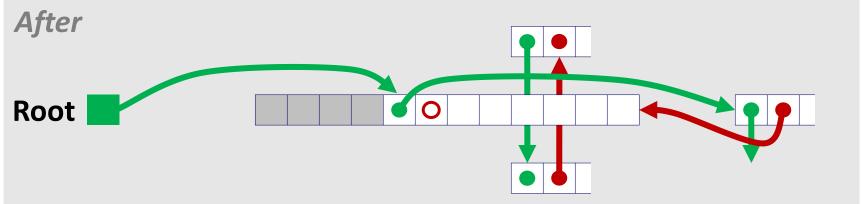

Insert the freed block at the root of the list

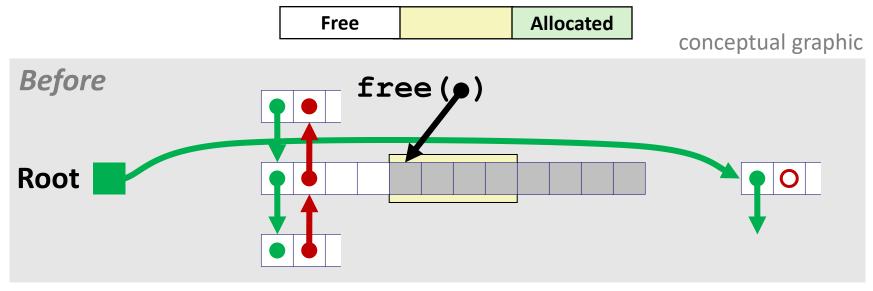

Freeing With a LIFO Policy (Case 2)

 Splice out adjacent successor block, coalesce both memory blocks, and insert the new block at the root of the list

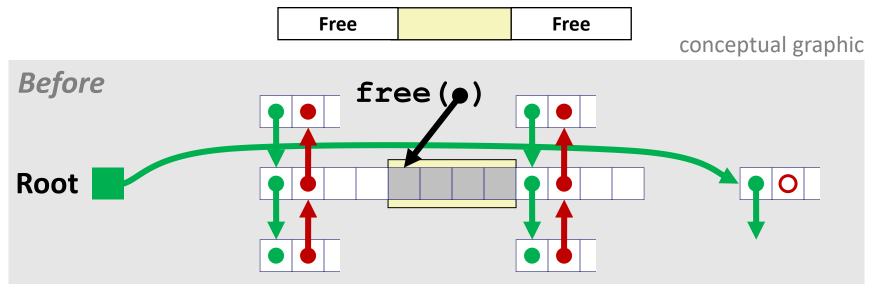

Freeing With a LIFO Policy (Case 3)

 Splice out adjacent predecessor block, coalesce both memory blocks, and insert the new block at the root of the list

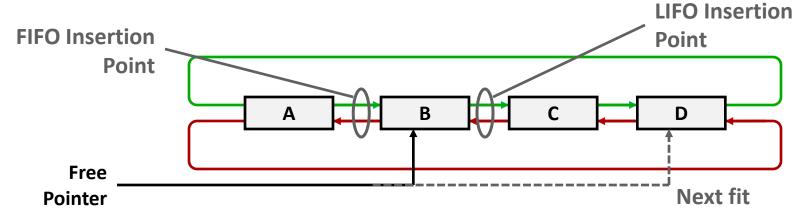

Freeing With a LIFO Policy (Case 4)

 Splice out adjacent predecessor and successor blocks, coalesce all 3 blocks, and insert the new block at the root of the list

Some Advice: An Implementation Trick

- Use circular, doubly-linked list
- Support multiple approaches with single data structure
- First-fit vs. next-fit
 - Either keep free pointer fixed or move as search list
- LIFO vs. FIFO
 - Insert as next block (LIFO), or previous block (FIFO)

Explicit List Summary

Comparison to implicit list:

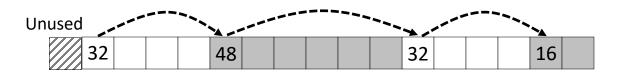

- Allocate is linear time in number of free blocks instead of all blocks
 - Much faster when most of the memory is full
- Slightly more complicated allocate and free because need to splice blocks in and out of the list
- Some extra space for the links (2 extra words needed for each block)
 - Does this increase internal fragmentation?

Today

- **Explicit free lists**
- Segregated free lists
- Memory-related perils and pitfalls

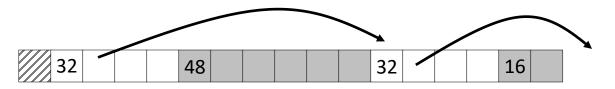

Keeping Track of Free Blocks

■ Method 1: *Implicit list* using length—links all blocks

Need to tag each block as allocated/free

Method 2: Explicit list among the free blocks using pointers

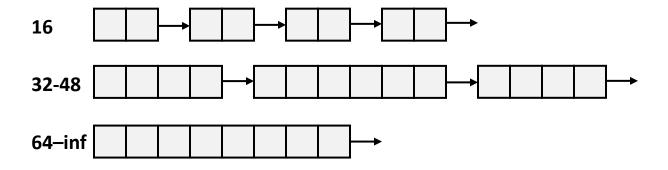

Need space for pointers

- Method 3: Segregated free list
 - Different free lists for different size classes.
- Method 4: *Blocks sorted by size*
 - Can use a balanced tree (e.g. Red-Black tree) with pointers within each free block, and the length used as a key

Segregated List (Seglist) Allocators

Each size class of blocks has its own free list

- Often have separate classes for each small size
- For larger sizes: One class for each size $[2^i + 1, 2^{i+1}]$

Seglist Allocator

Given an array of free lists, each one for some size class

■ To allocate a block of size n:

- Search appropriate free list for block of size m > n (i.e., first fit)
- If an appropriate block is found:
 - Split block and place fragment on appropriate list
 - If no block is found, try next larger class
- Repeat until block is found

If no block is found:

- Request additional heap memory from OS (using sbrk ())
- Allocate block of n bytes from this new memory
- Place remainder as a single free block in appropriate size class.

Seglist Allocator (cont.)

- To free a block:
 - Coalesce and place on appropriate list
- Advantages of seglist allocators vs. non-seglist allocators (both with first-fit)
 - Higher throughput
 - log time for power-of-two size classes vs. linear time
 - Better memory utilization
 - First-fit search of segregated free list approximates a best-fit search of entire heap.
 - Extreme case: Giving each block its own size class is equivalent to best-fit.

Quiz Time!

Canvas Quiz: Day 15 – Malloc Advanced

Today

- **Explicit free lists**
- Segregated free lists
- Memory-related perils and pitfalls

Memory-Related Perils and Pitfalls

- Dereferencing bad pointers
- Reading uninitialized memory
- Overwriting memory
- Referencing nonexistent variables
- Freeing blocks multiple times
- Referencing freed blocks
- Failing to free blocks

Dereferencing Bad Pointers

■ The classic scanf bug

```
int val;
...
scanf("%d", val);
```

Reading Uninitialized Memory

Assuming that heap data is initialized to zero

```
/* return y = Ax */
int *matvec(int **A, int *x) {
   int *y = malloc(N*sizeof(int));
   int i, j;
   for (i=0; i<N; i++)
      for (j=0; j<N; j++)
         y[i] += A[i][j]*x[j];
   return y;
```

Can avoid by using calloc

Overwriting Memory

Allocating the (possibly) wrong sized object

```
int **p;

p = malloc(N*sizeof(int));

for (i=0; i<N; i++) {
   p[i] = malloc(M*sizeof(int));
}</pre>
```

Can you spot the bug?

Off-by-one errors

```
char **p;

p = malloc(N*sizeof(int *));

for (i=0; i<=N; i++) {
   p[i] = malloc(M*sizeof(int));
}</pre>
```

```
char *p;

p = malloc(strlen(s));
strcpy(p,s);
```

Not checking the max string size

```
char s[8];
int i;

gets(s); /* reads "123456789" from stdin */
```

Basis for classic buffer overflow attacks

Misunderstanding pointer arithmetic

```
int *search(int *p, int val) {
   while (p && *p != val)
      p += sizeof(int);

   return p;
}
```

Referencing a pointer instead of the object it points to

```
int *BinheapDelete(int **binheap, int *size) {
   int *packet;
   packet = binheap[0];
   binheap[0] = binheap[*size - 1];
   *size--;
   Heapify(binheap, *size, 0);
   return(packet);
}
```

- What gets decremented?
 - (See next slide)

C operators

- ->, (), and [] have high precedence, with * and & just below
- Unary +, -, and * have higher precedence than binary forms

Referencing a pointer instead of the object it points to

```
int *BinheapDelete(int **binheap, int *size) {
   int *packet;
   packet = binheap[0];
   binheap[0] = binheap[*size - 1];
   *size--;
   Heapify(binheap, *size, 0);
   return(packet);
}
Operators
() [] -> . ++(--)

Associativity
left to right
```

Same effect as

```
size--;
```

Rewrite as

```
(*size) --;
```

Referencing Nonexistent Variables

Forgetting that local variables disappear when a function returns

```
int *foo () {
   int val;

return &val;
}
```

Freeing Blocks Multiple Times

Nasty!

Referencing Freed Blocks

Evil!

Failing to Free Blocks (Memory Leaks)

Slow, long-term killer!

```
foo() {
   int *x = malloc(N*sizeof(int));
   ...
   return;
}
```

Failing to Free Blocks (Memory Leaks)

Freeing only part of a data structure

```
struct list {
   int val;
   struct list *next;
};
foo() {
   struct list *head = malloc(sizeof(struct list));
  head->val = 0;
  head->next = NULL;
   <create and manipulate the rest of the list>
   free (head) ;
   return;
```

Dealing With Memory Bugs

- Debugger: gdb
 - Good for finding bad pointer dereferences
 - Hard to detect the other memory bugs
- Data structure consistency checker
 - Runs silently, prints message only on error
 - Use as a probe to zero in on error
- Binary translator: valgrind
 - Powerful debugging and analysis technique
 - Rewrites text section of executable object file
 - Checks each individual reference at runtime
 - Bad pointers, overwrites, refs outside of allocated block
- glibc malloc contains checking code
 - setenv MALLOC_CHECK_ 3

Supplemental slides

Implicit Memory Management: Garbage Collection

■ Garbage collection: automatic reclamation of heap-allocated storage—application never has to explicitly free memory

```
void foo() {
  int *p = malloc(128);
  return; /* p block is now garbage */
}
```

- **■** Common in many dynamic languages:
 - Python, Ruby, Java, Perl, ML, Lisp, Mathematica
- Variants ("conservative" garbage collectors) exist for C and C++
 - However, cannot necessarily collect all garbage

Garbage Collection

How does the memory manager know when memory can be freed?

- In general we cannot know what is going to be used in the future since it depends on conditionals
- But we can tell that certain blocks cannot be used if there are no pointers to them

Must make certain assumptions about pointers

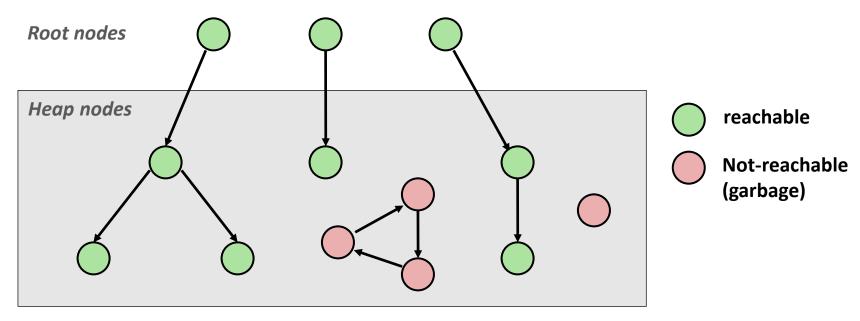

- Memory manager can distinguish pointers from non-pointers
- All pointers point to the start of a block
- Cannot hide pointers
 (e.g., by coercing them to an int, and then back again)

Classical GC Algorithms

- Mark-and-sweep collection (McCarthy, 1960)
 - Does not move blocks (unless you also "compact")
- Reference counting (Collins, 1960)
 - Does not move blocks (not discussed)
- Copying collection (Minsky, 1963)
 - Moves blocks (not discussed)
- Generational Collectors (Lieberman and Hewitt, 1983)
 - Collection based on lifetimes
 - Most allocations become garbage very soon
 - So focus reclamation work on zones of memory recently allocated
- For more information: Jones and Lin, "Garbage Collection: Algorithms for Automatic Dynamic Memory", John Wiley & Sons, 1996.

Memory as a Graph

- We view memory as a directed graph
 - Each block is a node in the graph
 - Each pointer is an edge in the graph
 - Locations not in the heap that contain pointers into the heap are called root nodes (e.g. registers, locations on the stack, global variables)

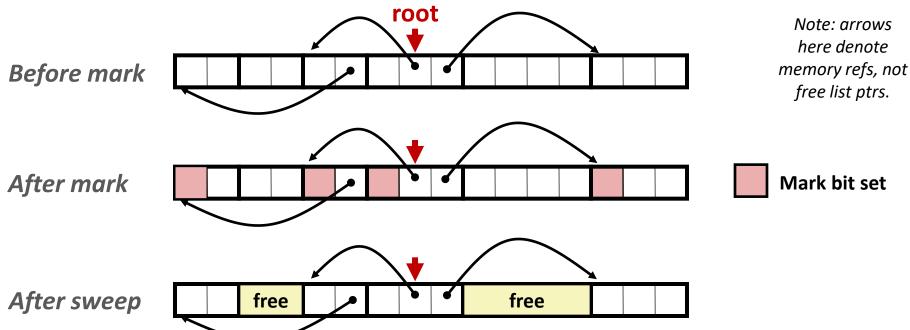

A node (block) is *reachable* if there is a path from any root to that node.

Non-reachable nodes are *garbage* (cannot be needed by the application)

Mark and Sweep Collecting

- Can build on top of malloc/free package
 - Allocate using malloc until you "run out of space"
- When out of space:
 - Use extra mark bit in the head of each block
 - Mark: Start at roots and set mark bit on each reachable block
 - Sweep: Scan all blocks and free blocks that are not marked

Assumptions For a Simple Implementation

Application

- new(n): returns pointer to new block with all locations cleared
- read(b,i): read location i of block b into register
- write(b,i,v): write v into location i of block b

Each block will have a header word

- addressed as b[-1], for a block b
- Used for different purposes in different collectors

Instructions used by the Garbage Collector

- is_ptr(p): determines whether p is a pointer
- length (b): returns the length of block b, not including the header
- get roots(): returns all the roots

```
ptr mark(ptr p) {
   if (!is_ptr(p)) return;
   if (markBitSet(p)) return;
   setMarkBit(p);
   for (i=0; i < length(p); i++)
      mark(p[i]);
   return;
}</pre>
```

Mark using depth-first traversal of the memory graph

C Pointer Declarations: Test Yourself!

int	*p	p is a pointer to int
int	*p[13]	p is an array[13] of pointer to int
int	*(p[13])	p is an array[13] of pointer to int
int	**p	p is a pointer to a pointer to an int
int	(*p) [13]	p is a pointer to an array[13] of int
int	*f()	f is a function returning a pointer to int
int	(*f)()	f is a pointer to a function returning int
int	(*(*x[3])())[5]	x is an array[3] of pointers to functions returning pointers to array[5] of ints

C Pointer Declarations: Test Yourself!

int	*p	p is a pointer to int
int	*p[13]	p is an array[13] of pointer to int
int	*(p[13])	p is an array[13] of pointer to int
int	**p	p is a pointer to a pointer to an int
int	(*p) [13]	p is a pointer to an array[13] of int
int	*f()	f is a function returning a pointer to int
int	(*f)()	f is a pointer to a function returning int
int	(*(*x[3])())[5]	x is an array[3] of pointers to functions returning pointers to array[5] of ints
int	(*(*f())[13])()	f is a function returning ptr to an array[13] of pointers to functions returning int

Parsing: int (*(*f())[13])()

```
int (*(*f())[13])()
                        f is a function
int (*(*f())[13])()
int (*(*f())[13])()
                        f is a function
                        that returns a ptr
int (*(*f())[13])()
                        f is a function
                        that returns a ptr to an
                        array of 13
int (*(*f())[13])()
                        f is a function that returns
                        a ptr to an array of 13 ptrs
int (*(*f())[13])()
                        f is a function that returns
                        a ptr to an array of 13 ptrs
                        to functions returning an int
```
