# **Partial Redundancy Elimination**

#### 15-411/15-611 Compiler Design

Seth Copen Goldstein

November 2, 2021 (remember to Vote!)

# **Today**

- Lab5/Lab6 options
- Guest lectures
- PRE

#### Lab5 and Lab6

- Two options.
- Option 1: Lab5 (reduced) + Lab6
- Option 2: Lab5 + extra

Date	L5 & L6	L5++
11/11	assignments out	assignment out
11/16	L5 checkpoint	L5 checkpoint
11/18	L6 draft proposal	L5 extra opt draft proposal
11/20	feedback returned	feedback returned
11/23	L6 final proposal	L5 extra final proposal + sample C0 program(s)
11/27	L5 compiler & Report	
12/7		L5 compiler due
12/14	L6 compiler & report	L5 report due

# **Scoring**

- Option 1: L5-- 125 points, L6 175 points
  - Will adjust opt scaling down
  - Will scale down report requirements on L5
- Option 2: L5++ 300 points
  - require at least one loop opt, one whole program opt
  - At least one opt not covered in class
  - SSA (not required to do regalloc on SSA)
  - Require sample programs in addition to our benchmarks for your proposed opts

#### **Guest Lectures**

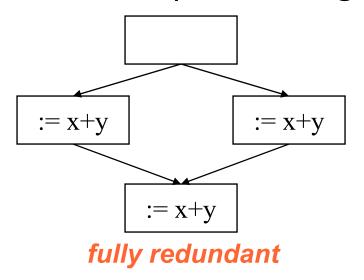

- Attendance mandatory
- Will be remote (on lecture zoom link)
- Tue 11/9, Bodo.ai
- Thr 11/11, Jane Street
- Tue 11/30, Google @ 4:30pm

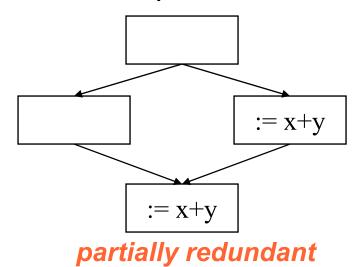

#### **Common Subexpression Elimination**

- Find computations that are always performed at least twice on an execution path and eliminate all but the first
- Usually limited to algebraic expressions
  - put in some canonical form
- Almost always improves performance
  - except when?

#### **CSE** Limitation

- Searches for "totally" redundant expressions
  - An expression is totally redundant if it is recomputed along all paths leading to the redundant expression
  - An expression is partially redundant if it is recomputed along some but not all paths

# **Loop-Invariant Code Motion**

- Moves computations that produce the same value on every iteration of a loop outside of the loop
- When is a statement loop invariant?
  - when all its operands are loop invariant...

# **Loop Invariance**

- An operand is loop-invariant if
  - 1.it is a constant,
  - 2.all definitions (use ud-chain) are located outside the loop, or
  - 3.has a single definitions (ud-chain again) which is inside the loop and that definition is itself loop invariant
- Can use iterative algorithm to compute loop invariant statements

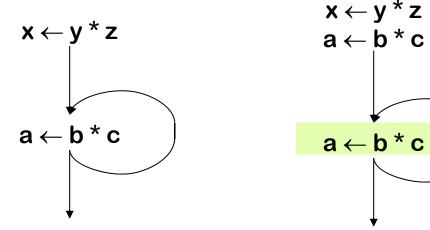

### **Loop Invariant Code Motion**

- Naïve approach: move all loop-invariant statements to the preheader
- Not always valid for statements which define variables
- If statement s defines v, can only move s if
  - -s dominates all uses of v in the loop
  - -s dominates all loop exits

# **Loop Invariant Code Motion**

 Loop invariant expressions are a form of partially redundant expressions. Why?

\*

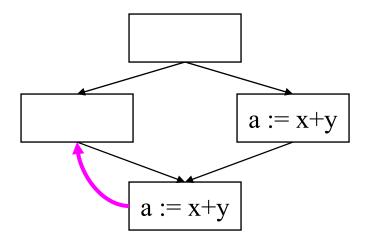

# **Partial Redundancy Elimination**

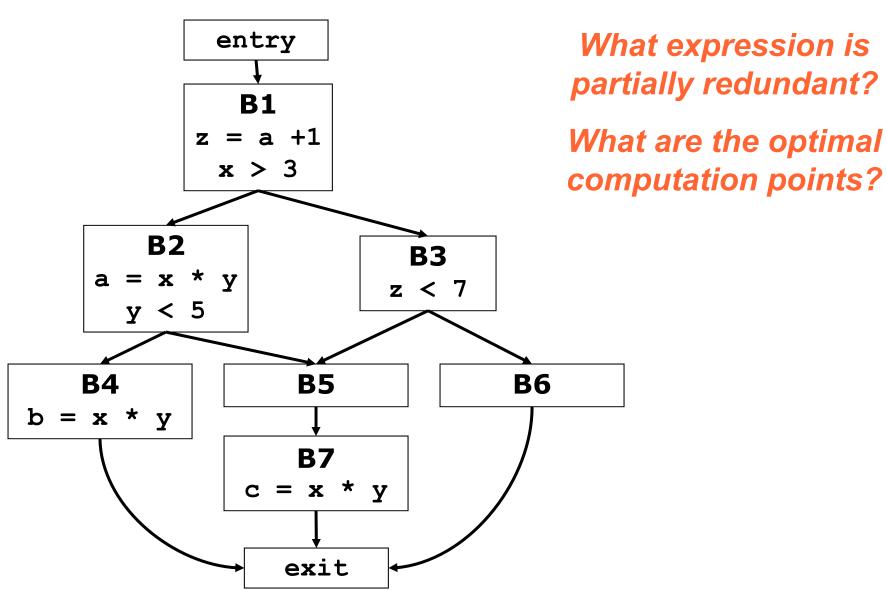

- Moves computations that are at least partially redundant to their optimal computation points and eliminates totally redundant ones
- Encompasses CSE and loop-invariant code motion

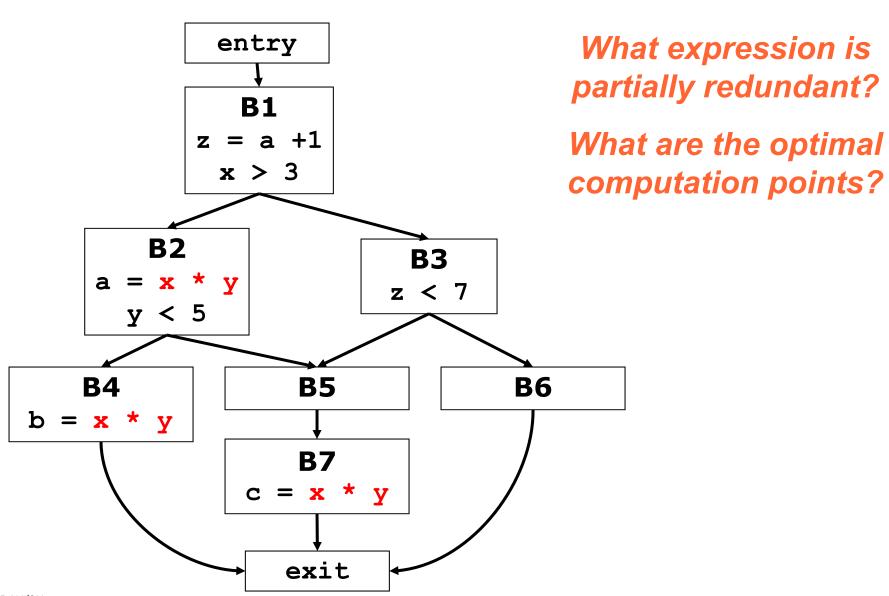

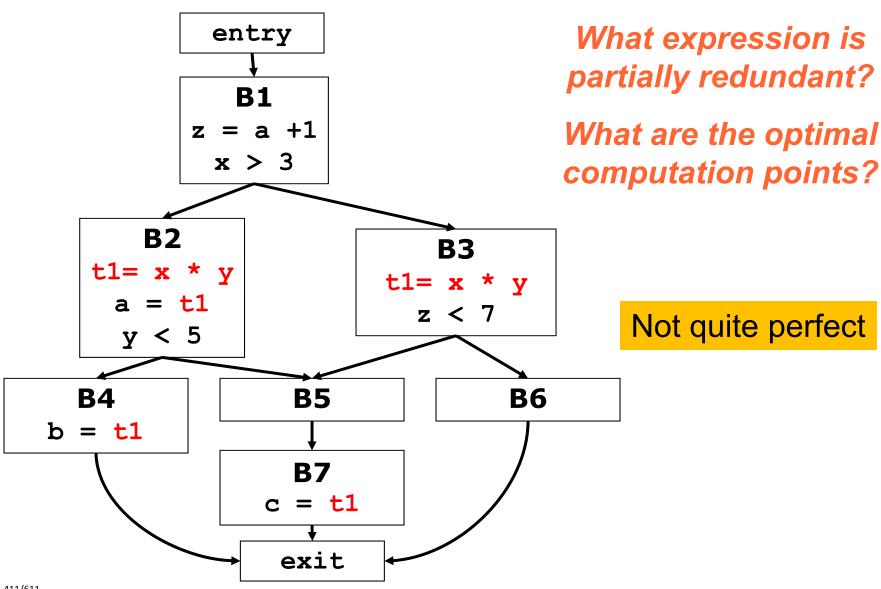

# **Optimal Computation Point**

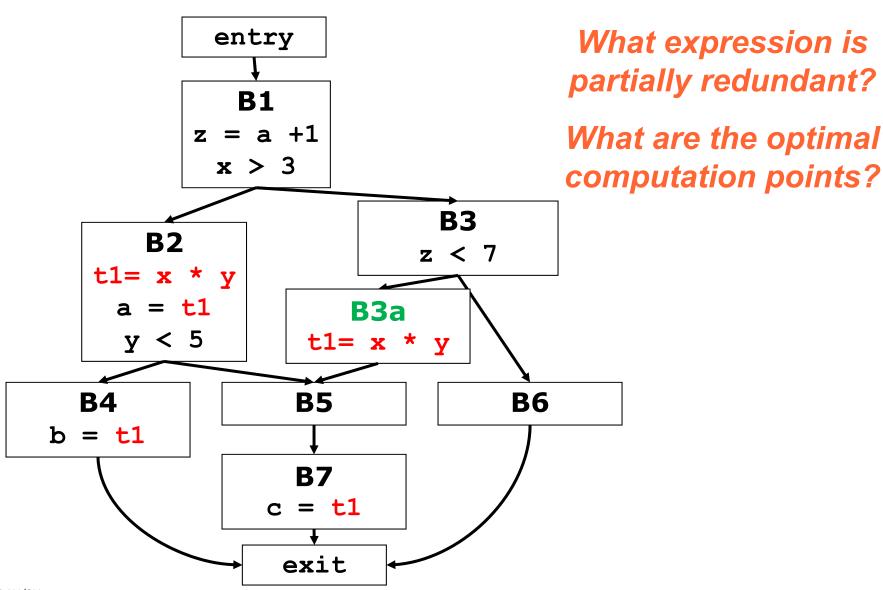

- •Optimal?
  - Result used and never recalculated
  - Expression placed late as possible Why?

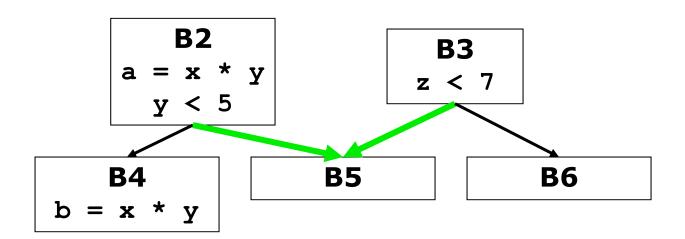

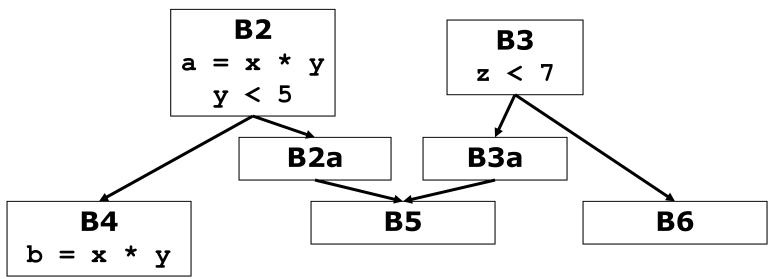

# **Critical Edge Splitting**

- •In order for PRE to work well, we must split critical edges
- •A *critical edge* is an edge that connects a block with multiple successors to a block with multiple predecessors

# **Critical Edge Splitting**

- •In order for PRE to work well, we must split critical edges
- •A *critical edge* is an edge that connects a block with multiple successors to a block with multiple predecessors

### **PRE History**

- PRE was first formulated as a bidirectional data flow analysis by Morel and Renvoise in 1979
- •Knoop, Rüthing, and Steffen came up with a way to do it using several unidirectional analysis in 1992 (called their approach *lazy code motion*)
  - this is a much simpler method
  - but it is still very complicated
- Kennedy etal reengineer the algorithm to work in SSA in 1999. See toplas

#### The 60K Plan

Find Earliest and useful

Determine for each expression the earliest place(s) it can be computed while still guaranteeing that it will be used

Find latest but needed

Postpone the expression as long as possible without introducing redundancy

Trading size for speed
 An expression may be computed in many places, but never if already computed

# General Approach to analysis

- Computationally Optimal Placement
  - Anticipatable computing exp is useful along any path to exit
  - Earliest
     p is the earliest point to compute exp
  - Expression can be placed at Ant 

     — Earliest
  - Increases register Pressure
- Lazy Code Motion

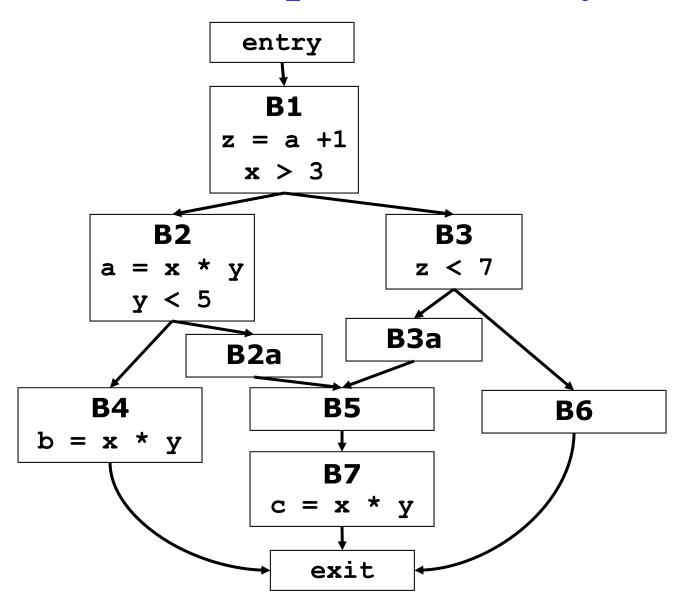

# General Approach to analysis

- Computationally Optimal Placement
- Lazy Code Motion
  - Latest
     Cannot move expression past p on any path
  - Isolated all uses of expression follow immediately after p

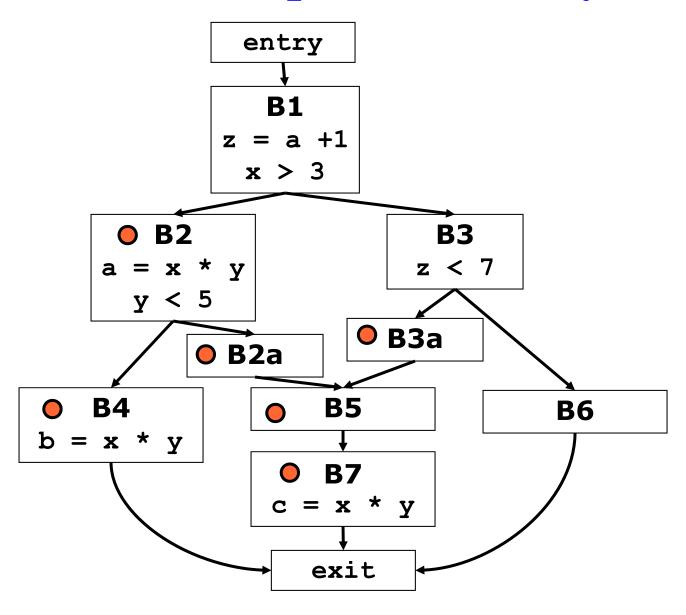

# **Anticipatable Expressions**

- Expression x+y is anticipated at a point p if x+y is guaranteed to be computed along any path from p->exit before any recomputation of x or y
- What kind of data flow is this?
  - backwards
  - intersection

# Anticipated for 'x\*y'?

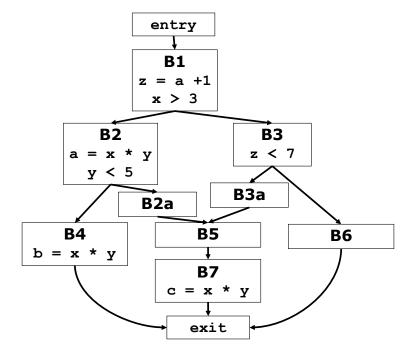

# Anticipated for 'x\*y'?

# Local Transparency (TRANSloc)

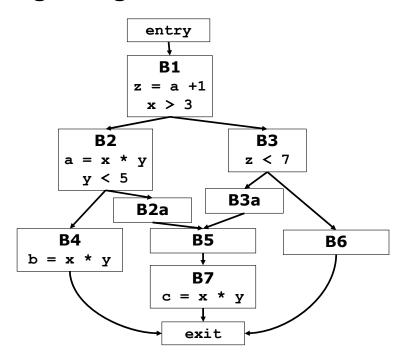

- •An expression's value is *locally transparent* in a block if there are no assignments in the block to variables within the expression
  - ie, expression not killed

Block	TRANSloc
entry	{a+1,x*y}
B1	{a+1,x*y}
B2	{x*y}
B2a	{a+1,x*y}
B3	{a+1,x*y}
B3a	{a+1,x*y}
B4	{a+1,x*y}
B5	{a+1,x*y}
B6	{a+1,x*y}
B7	{a+1,x*y}
exit	{a+1,x*y}

# Local Anticipatable (ANTloc)

- •An expression's value is *locally* anticipatable in a block if
  - there is a computation of the expression in the block
  - the computation can be safely moved to the beginning of the block

ANTIOC
{}
{a+1}
{x*y}
{}
{}
{}
{x*y}
{}
{}
{x*y}
{}

# Globally Anticipatable (ANT)

- •An expression's value is *globally* anticipatable on entry to a block if
  - every path from this point to exit includes a computation of the expression
  - it would be valid to place a computation of an expression anywhere along these paths

This is like liveness, only for expressions

# Globally Anticipatable (ANT)

$$ANTin(i) = ANTloc(i) \cup (TRANSloc(i) \cap ANTout(i))$$

$$ANTout(i) = \bigcap_{j \in succ(i)} ANTin(j)$$

 $ANTout(exit) = \{\}$ 

Block	ANTin	ANTout
entry	{a+1}	{a+1}
B1	{a+1}	{}
B2	{x*y}	{x*y}
B2a	{x*y}	{x*y}
В3	{}	{}
ВЗа	{x*y}	{x*y}
B4	{x*y}	{}
B5	{x*y}	{x*y}
В6	{}	{}
B7	{x*y}	{}
exit	{}	{}

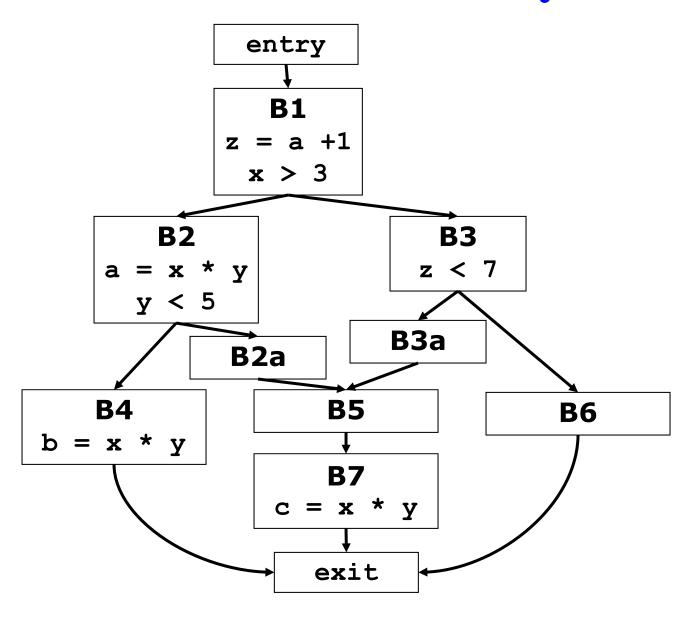

### Earliest (EARL)

- An expression's value is earliest on entry to a block if
  - no path from entry to the block evaluates the expression to produce the same value as evaluating it at the block's entry would

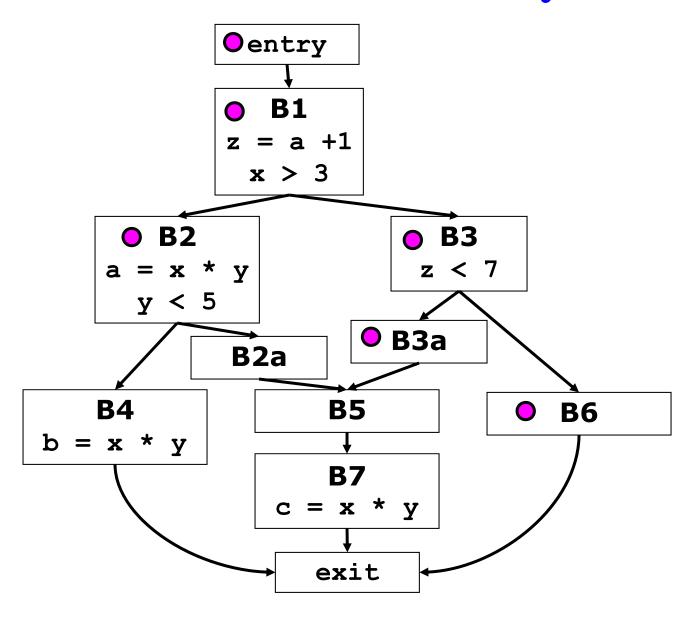

#### **Intuition:**

- at this point if we compute the expression we are computing something completely new
- says nothing about usefulness of computing expression

# Earliest for 'x\*y'?

# Earliest for 'x\*y'?

$$EARLin(i) = \bigcap_{j \in pred(i)} EARLout(j)$$

# **Computationally Optimal**

 It is computationally optimal to compute expression at entry to block if

 $\exp \in ANTin(block) \cap EARLin(block)$ 

• But, it may increase register pressure.

# Anticipated for 'x\*y' at input?

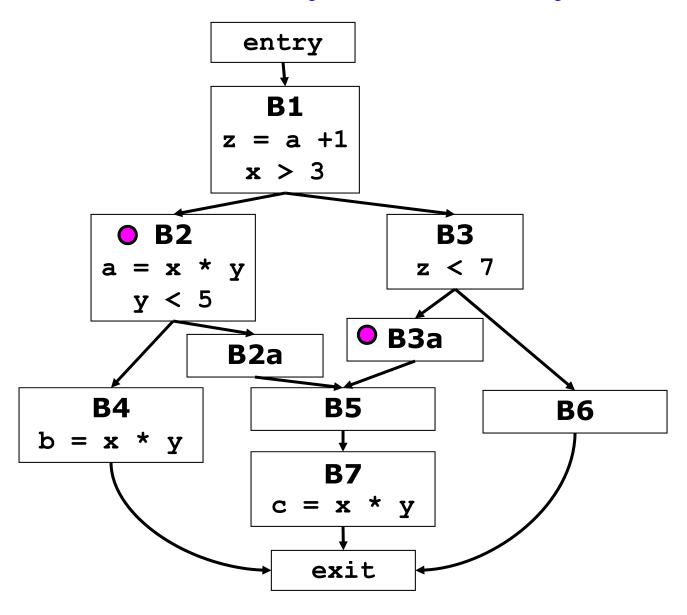

### **Anticipated & Early (at input)**

# **Delayedness (DELAY)**

- An expression is delayed on entry to a block if
  - All paths from entry to block contain an anticipatable and early computation of exp (could be this block) AND all uses of exp follow this block.
  - I.e., exp can be delayed to at least this block.

# Delayed for 'x\*y'

### **Delayedness (DELAY)**

$$DELAYin(i) = (ANTin(i) \cap EARLin(i)) \cup \bigcap_{j \in pred(i)} DELAYout(j)$$

 $DELAYout(i) = ANTloc(i) \cap DELAYin(i)$ 

 $DELAYin(entry) = ANTin(entry) \cap EARLin(entry)$ 

Block	ANTin(i) ∩ EARLin(i)
entry	{a+1}
B2	{x*y}
ВЗа	{x*y}

Block	DELAYin	DELAYout
entry	{a+1}	{a+1}
B1	{a+1}	{}
B2	{x*y}	{}
B2a	{}	{}
В3	{}	{}
B3a	{x*y}	{x*y}
B4	{}	{}
B5	{}	{}
B6	{}	{}

#### Lateness (LATE)

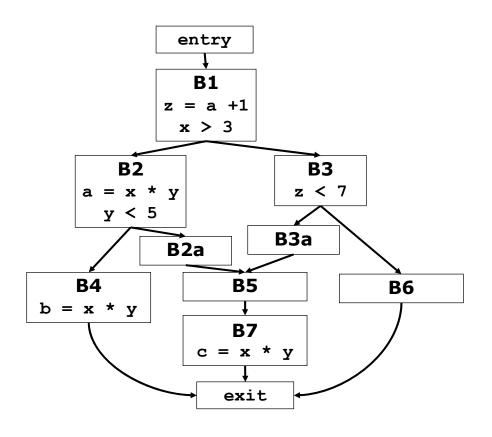

- An expression is *latest* on entry to a block if
  - it is the optimal point for computing the expression and
  - on every path from the block entry to exit, any other optimal computation point occurs after an expression computation in the original flowgraph

i.e., there is no "later" placement for this expression

#### Latestness (LATE)

$$LATEin(i) = DELAYin(i) \cap \left(ANTloc(i) \cup \bigcap_{j \in succ(i)} DELAYin(j)\right)$$

Block	LATEin
entry	{}
B1	{a+1}
B2	{x*y}
B2a	{}
В3	{}
ВЗа	{x*y}
B4	{}
B5	{}
В6	{}
B7	{}
exit	{}

#### **Isolatedness (ISOL)**

- •An optimal placement in a block for the computation of an expression is *isolated* iff
  - on every path from a successor of the block to the exit block, every original computation is preceded by the optimal placement point

#### **Isolatedness (ISOL)**

$$ISOLin(i) = LATEin(i) \cup \left(\overline{ANTloc(i)} \cap ISOLout(i)\right)$$

$$ISOLout(i) = \bigcap_{j \in succ(i)} ISOLin(j)$$

$$ISOLout(exit) = \{\}$$

Block	ISOLin	<b>ISOLout</b>
entry	{}	{}
B1	{a+1}	{}
B2	{x*y}	{}
B2a	{}	{}
В3	{}	{}
ВЗа	{x*y}	{}
B4	{}	{}
B5	{}	{}
В6	{}	{}
B7	{}	{}
exit	{}	{}

### **Optimal Placement**

•The set of expression for which a given block is the optimal computation point is the set of expressions that are latest and not isolated

$$OPT(i) = LATEin(i) \cap ISOLout(i)$$

### **Redundant Computations**

 The set of redundant expressions in a block consist of those used in the block that are neither isolated nor latest

$$REDN(i) = ANTloc(i) \cap \overline{LATEin(i) \cup ISOLout(i)}$$

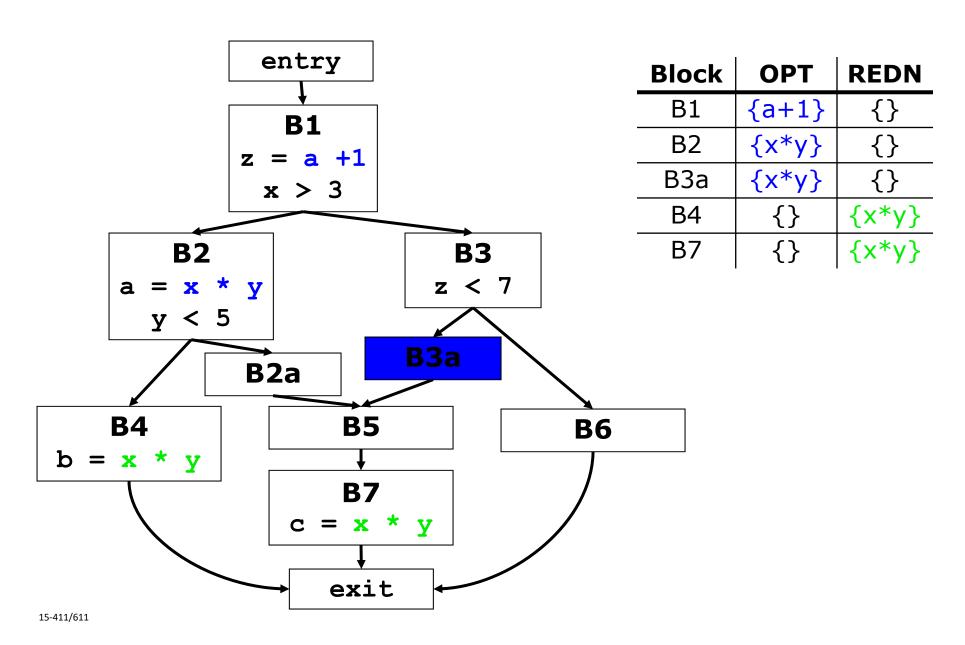

#### **OPT and REDN**

insert these
(if necessary)

Block	OPT	REDN
entry	{}	{}
B1	{a+1}	{}
B2	{x*y}	{}
B2a	{}	{}
В3	{}	{}
ВЗа	{x*y}	{}
B4	{}	{x*y}
B5	{}	{}
B6	{}	{}
B7	{}	{x*y}
exit	{}	{}

- remove these
