Deep Learning Sequence to Sequence models: Attention Models

Sequence-to-sequence modelling

- Problem:
 - A sequence $X_1 \dots X_N$ goes in
 - A different sequence $Y_1 \dots Y_M$ comes out
- E.g.
 - Speech recognition: Speech goes in, a word sequence comes out
 - Alternately output may be phoneme or character sequence
 - Machine translation: Word sequence goes in, word sequence comes out
- In general $N \neq M$
 - No synchrony between X and Y.

- Sequence goes in, sequence comes out
- No notion of "synchrony" between input and output
 - May even not have a notion of "alignment"
 - E.g. "I ate an apple" \rightarrow "Ich habe einen apfel gegessen"

- The input and output sequences happen in the same order
 - Although they may be asynchronous
 - E.g. Speech recognition
 - The input speech corresponds to the phoneme sequence output

Today

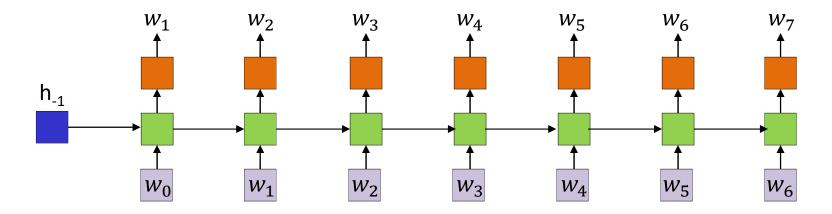

- Sequence goes in, sequence comes out
- No notion of "synchrony" between input and output
 - May even not have a notion of "alignment"
 - E.g. "I ate an apple" → "Ich habe einen apfel gegessen"

Recap: Predicting text

 Simple problem: Given a series of symbols (characters or words) w₁ w₂... w_n, predict the next symbol (character or word) w_{n+1}

Simple recurrence : Text Modelling

- Learn a model that can predict the next character given a sequence of characters

 Or, at a higher level, words
- After observing inputs $w_0 \dots w_k$ it predicts w_{k+1}

Language modelling using RNNs

Four score and seven years ???

ABRAHAMLINCOL??

• Problem: Given a sequence of words (or characters) predict the next one

- Input: symbols as one-hot vectors
 - Dimensionality of the vector is the size of the "vocabulary"
 - Projected down to lower-dimensional "embeddings"
- Output: Probability distribution over symbols

$$Y(t, i) = P(V_i | w_0 \dots w_{t-1})$$

- V_i is the i-th symbol in the vocabulary
- Divergence

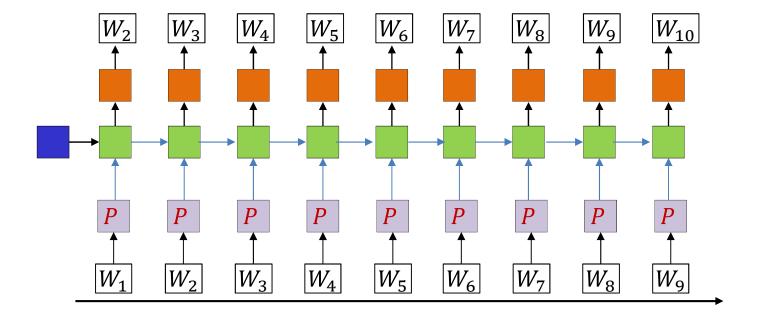

$$Div(\mathbf{Y}_{target}(1 \dots T), \mathbf{Y}(1 \dots T)) = \sum_{t} Xent(\mathbf{Y}_{target}(t), \mathbf{Y}(t)) = -\sum_{t} \log Y(t, w_{t+1})$$

9

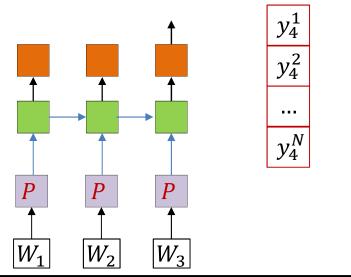

The probability assigned

to the correct next word

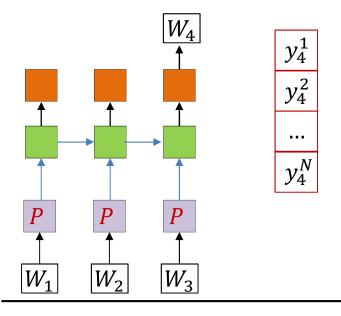

Generating Language: The model

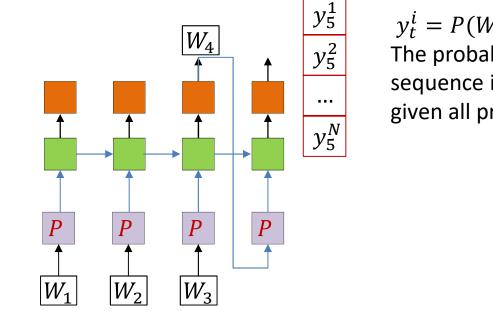

- The hidden units are (one or more layers of) LSTM units
- Trained via backpropagation from a lot of text

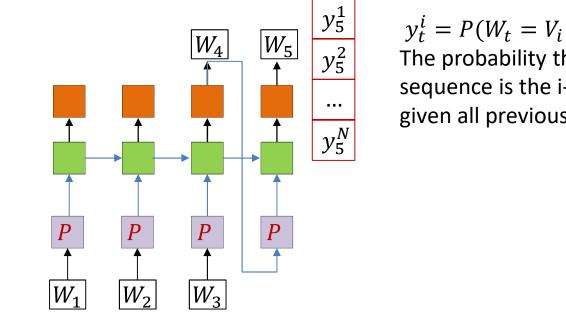

- On trained model : Provide the first few words
 - One-hot vectors
- After the last input word, the network generates a probability distribution over words
 - Outputs an N-valued probability distribution rather than a one-hot vector

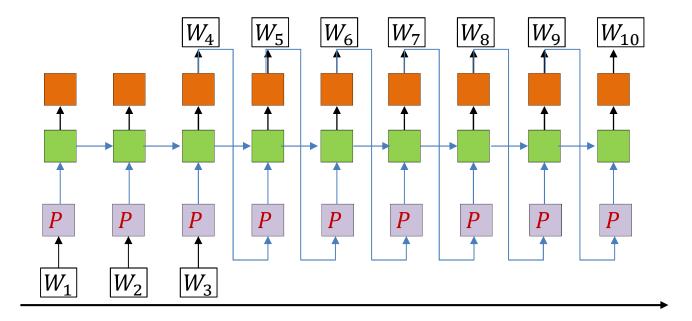

- On trained model : Provide the first few words
 - One-hot vectors
- After the last input word, the network generates a probability distribution over words
 - Outputs an N-valued probability distribution rather than a one-hot vector
- Draw a word from the distribution
 - And set it as the next word in the series

- Feed the drawn word as the next word in the series
 - And draw the next word from the output probability distribution

- Feed the drawn word as the next word in the series
 - And draw the next word from the output probability distribution

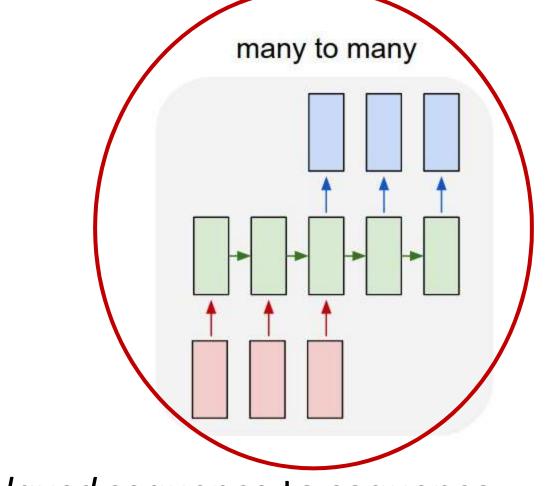

- Feed the drawn word as the next word in the series
 - And draw the next word from the output probability distribution
- Continue this process until we terminate generation
 - For text generation we will usually end at an <eos> (end of sequence) symbol
 - The <eos> symbol is a special symbol included in the vocabulary, which indicates the termination of a sequence and occurs only at the final position of sequences

Returning our problem

I ate an apple \rightarrow Seq2seq \rightarrow Ich habe einen apfel gegessen

- Problem:
 - A sequence $X_1 \dots X_N$ goes in
 - A different sequence $Y_1 \dots Y_M$ comes out
- Similar to predicting text, but with a difference
 - The output is in a different language..

Modelling the problem

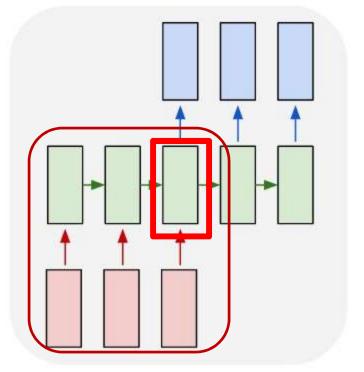

• *Delayed* sequence to sequence

Modelling the problem

many to many

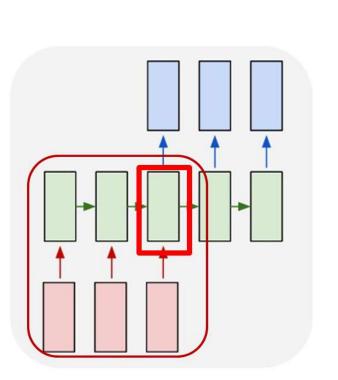

First process the input and generate a hidden representation for it

• *Delayed* sequence to sequence

Pseudocode

First run the inputs through the network
Assuming h(-1,1) is available for all layers
for t = 0:T-1 # Including both ends of the index
 [h(t),..] = RNN_input_step(x(t),h(t-1),...)
H = h(T-1)

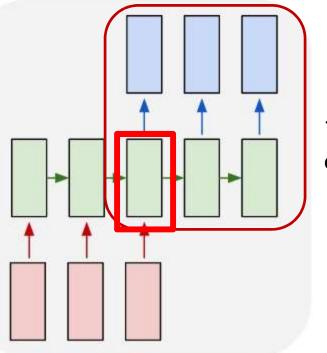

"RNN_input" may be a multi-layer RNN of any kind

Modelling the problem

many to many

First process the input and generate a hidden representation for it

Then use it to generate an output

• Delayed sequence to sequence

Pseudocode

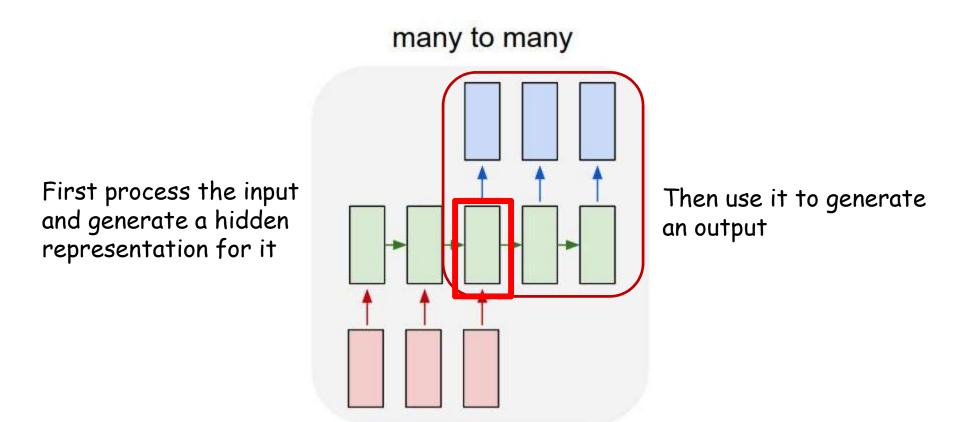

First run the inputs through the network
Assuming h(-1,1) is available for all layers
for t = 0:T-1 # Including both ends of the index
 [h(t),..] = RNN_input_step(x(t),h(t-1),...)
H = h(T-1)

```
# Now generate the output y_{out}(1), y_{out}(2), ...
t = 0
h_{out}(0) = H
do
  t = t+1
  [y(t), h_{out}(t)] = RNN_output_step(h_{out}(t-1))
  y<sub>out</sub>(t) = draw_word_from(y(t))
until y<sub>out</sub>(t) == <eos>
```

Pseudocode

First run the inputs through the network # Assuming h(-1,1) is available for all layers for t = 0:T-1 # Including both ends of the index [h(t),..] = RNN_input_step(x(t),h(t-1),...) H = h(T-1) The output at each time is a probability distribution over symbols. We draw a word from this distribution # Now generate the output $y_{out}(1)$, $y_{out}(2)$,... t = 0 $\mathbf{h}_{\mathbf{out}}(0) = \mathbf{H}$ do t = t+1 $[y(t), h_{out}(t)] = RNN_output_step(h_{out}(t-1))$ $y_{out}(t) = draw_word_from(y(t))$ until y_{out}(t) == <eos>

Modelling the problem

• *Problem:* Each word that is output depends only on current hidden state, and not on previous outputs

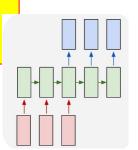

Pseudocode

Changing this output at time t does not affect the output at t+1

E.g. If we have drawn "It was a" vs "It was an", the probability lex that the next word is "dark" remains the same (dark must ideally not follow "an")

This is because the output at time t does not influence the computation at t+1

Now generate the output $y_{out}(1), y_{out}(2), ...$ t = 0

 $h_{1}(0) = H$

t = t+1 $[y(t), h_{out}(t)] = RNN_output_step(h_{out}(t-1))$ $y_{out}(t) = draw_word_from(y(t))$ until $y_{out}(t) == \langle eos \rangle$

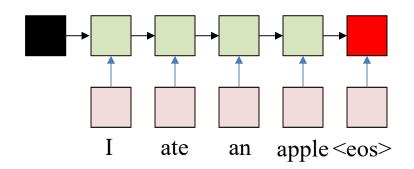

Modelling the problem

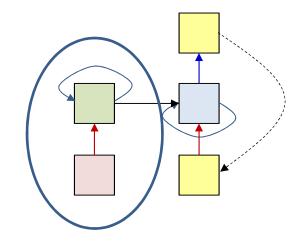

many to many

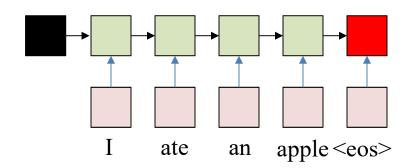

• *Delayed* sequence to sequence

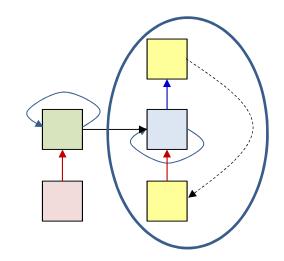

- Delayed *self-referencing* sequence-to-sequence

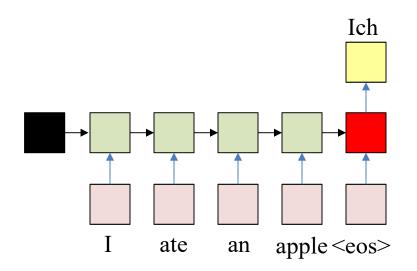

- The input sequence feeds into an recurrent structure
- The input sequence is terminated by an explicit <eos> symbol
 - The hidden activation at the <eos> "stores" all information about the sentence

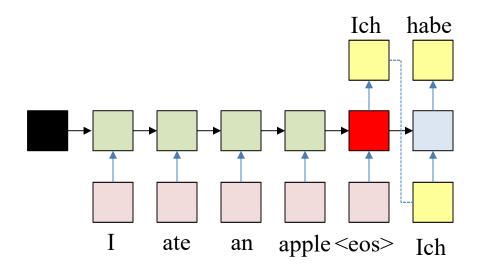

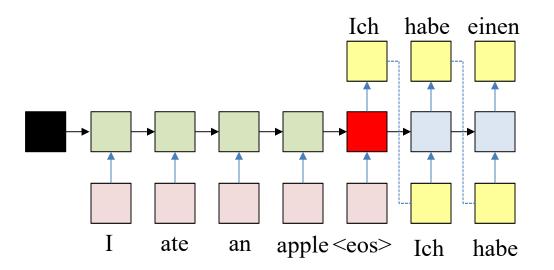

- The input sequence feeds into an recurrent structure
- The input sequence is terminated by an explicit <eos> symbol
 - The hidden activation at the <eos> "stores" all information about the sentence
- Subsequently a *second* RNN uses the hidden activation as initial state to produce a sequence of outputs
 - The output at each time becomes the input at the next time
 - Output production continues until an <eos> is produced

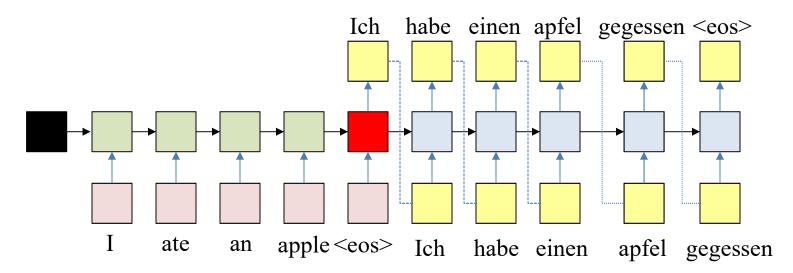

- The input sequence feeds into an recurrent structure
- The input sequence is terminated by an explicit <eos> symbol
 - The hidden activation at the <eos> "stores" all information about the sentence
- Subsequently a *second* RNN uses the hidden activation as initial state to produce a sequence of outputs
 - The output at each time becomes the input at the next time
 - Output production continues until an <eos> is produced

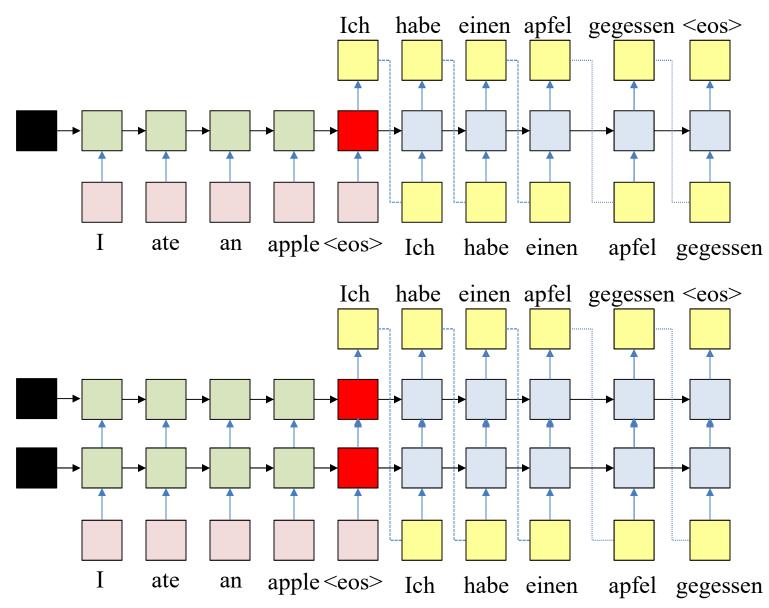

- The input sequence feeds into an recurrent structure
- The input sequence is terminated by an explicit <eos> symbol
 - The hidden activation at the <eos> "stores" all information about the sentence
- Subsequently a *second* RNN uses the hidden activation as initial state to produce a sequence of outputs
 - The output at each time becomes the input at the next time
 - Output production continues until an <eos> is produced

- The input sequence feeds into an recurrent structure
- The input sequence is terminated by an explicit <eos> symbol
 - The hidden activation at the <eos> "stores" all information about the sentence
- Subsequently a *second* RNN uses the hidden activation as initial state to produce a sequence of outputs
 - The output at each time becomes the input at the next time
 - Output production continues until an <eos> is produced

- The input sequence feeds into an recurrent structure
- The input sequence is terminated by an explicit <eos> symbol
 - The hidden activation at the <eos> "stores" all information about the sentence
- Subsequently a *second* RNN uses the hidden activation as initial state to produce a sequence of outputs
 - The output at each time becomes the input at the next time
 - Output production continues until an <eos> is produced

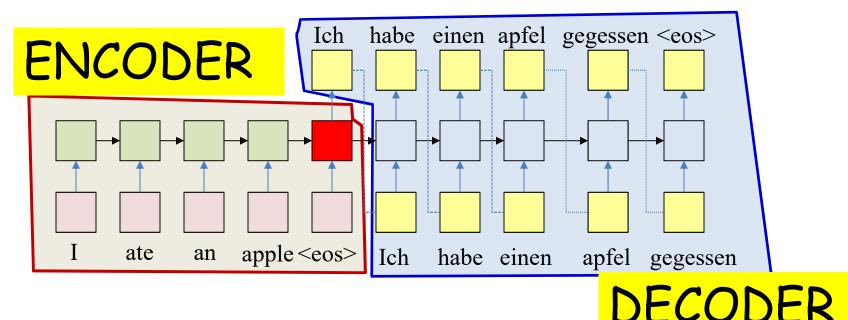

We will illustrate with a single hidden layer, but the discussion generalizes to more layers

Pseudocode

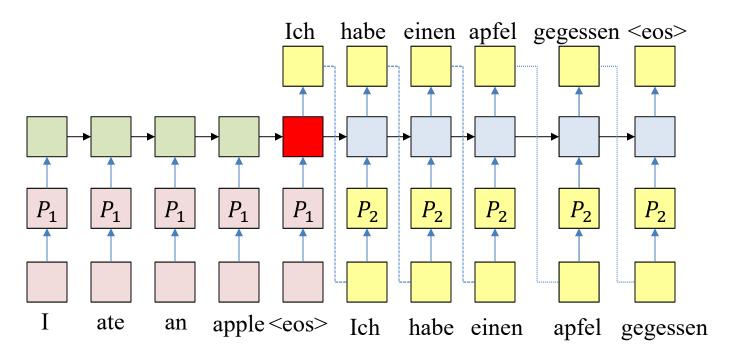

```
# First run the inputs through the network
# Assuming h(-1,1) is available for all layers
t = 0
do
     [h(t),..] = RNN input step(x(t),h(t-1),...)
until x(t) == "<eos>"
H = h(T-1)
# Now generate the output y_{out}(1), y_{out}(2),...
t = 0
\mathbf{h}_{out} (0) = \mathbf{H}
# Note: begins with a "start of sentence" symbol
#
     <sos> and <eos> may be identical
y_{out}(0) = \langle sos \rangle
do
    t = t+1
     [y(t), h_{out}(t)] = RNN_output_step(h_{out}(t-1), y_{out}(t-1))
     y_{out}(t) = draw word from(y(t))
until y<sub>out</sub>(t) == <eos>
```

Pseudocode

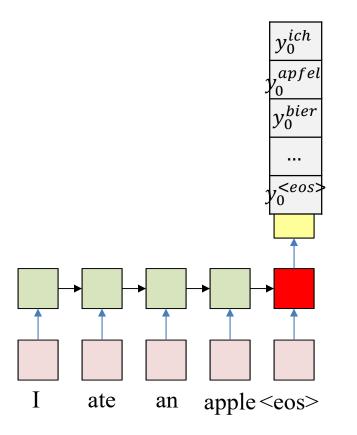

```
# First run the inputs through the network
# Assuming h(-1,1) is available for all layers
t = 0
do
     [h(t),..] = RNN input step(x(t),h(t-1),...)
until x(t) == "<eos>"
\mathbf{H} = \mathbf{h}(\mathbf{T}-1)
# Now generate the output y_{out}(1), y_{out}(2),...
t = 0
\mathbf{h}_{out}(0) = \mathbf{H}
# Note: begins with a "start of sentence" symbol
#
         <sos> and <eos> may be identical
y_{out}(0) = \langle sos \rangle
do
     t = t+1
     [y(t), h_{out}(t)] = RNN_output_step(h_{out}(t-1), y_{out}(t-1))
      y_{out}(t) = draw_word_from(y(t))
until y<sub>out</sub>(t) == <eos>
                                    Drawing a different word at t will change the
                                                                                34
                                    next output since y<sub>out</sub>(t) is fed back as input
```

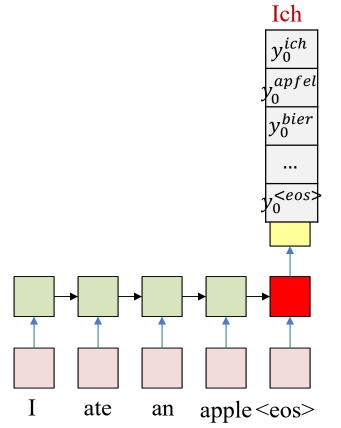

- The input sequence feeds into an recurrent structure
- The input sequence is terminated by an explicit <eos> symbol
 - The hidden activation at the <eos> "stores" all information about the sentence
- Subsequently a *second* RNN uses the hidden activation as initial state to produce a sequence of outputs
 - The output at each time becomes the input at the next time
 - Output production continues until an <eos> is produced

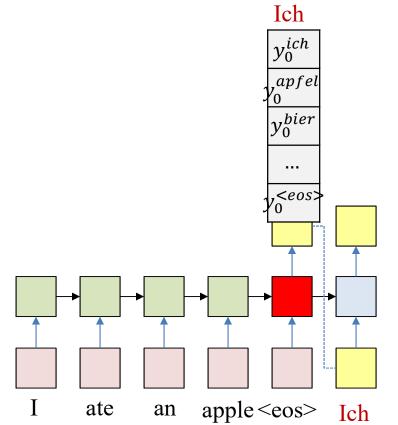

- A more detailed look: The one-hot word representations may be compressed via embeddings
 - Embeddings will be learned along with the rest of the net
 - In the following slides we will not represent the projection matrices

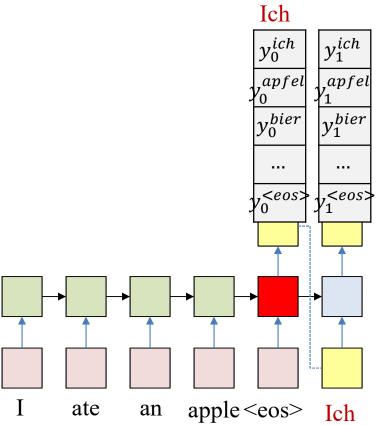

- At each time k the network actually produces a probability distribution over the output vocabulary
 - $y_k^w = P(O_k = w | O_{k-1}, \dots, O_1, I_1, \dots, I_N)$
 - The probability given the entire input sequence $I_1, ..., I_N$ and the partial output sequence $O_1, ..., O_{k-1}$ until k
- At each time a word is *drawn* from the output distribution
- The drawn word is provided as input to the next time

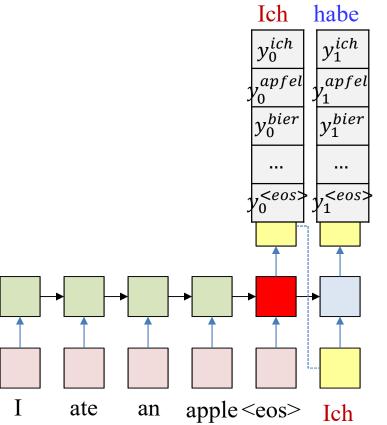

- At each time k the network actually produces a probability distribution over the output vocabulary
 - $y_k^w = P(O_k = w | O_{k-1}, \dots, O_1, I_1, \dots, I_N)$
 - The probability given the entire input sequence $I_1, ..., I_N$ and the partial output sequence $O_1, ..., O_{k-1}$ until k
- At each time a word is *drawn* from the output distribution
- The drawn word is provided as input to the next time

Generating an output from the net

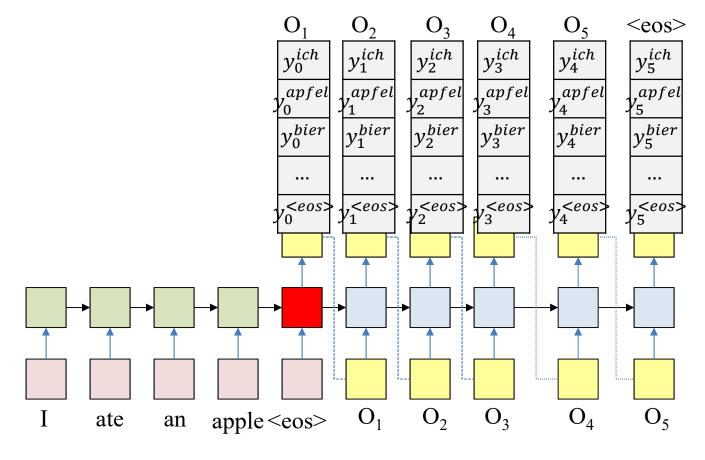

- At each time the network produces a probability distribution over words, given the entire input and previous outputs
- At each time a word is *drawn* from the output distribution
- The drawn word is provided as input to the next time
- The process continues until an <eos> is generated

Pseudocode

```
# First run the inputs through the network
# Assuming h(-1,1) is available for all layers
t = 0
do
     [h(t),..] = RNN input step(x(t),h(t-1),...)
until x(t) == "<eos>"
H = h(T-1)
# Now generate the output y_{out}(1), y_{out}(2),...
t = 0
\mathbf{h}_{out}(0) = \mathbf{H}
# Note: begins with a "start of sentence" symbol
#
        <sos> and <eos> may be identical
y_{out}(0) = \langle sos \rangle
do
    t = t+1
     [y(t), h_{out}(t)] = RNN_output_step(h_{out}(t-1), y_{out}(t-1))
     y_{out}(t) = draw_word_from(y(t))
until y<sub>out</sub>(t) == <eos>
                                What is this magic operation?
```

The probability of the output

 $P(O_1, \dots, O_L | W_1^{in}, \dots, W_N^{in}) = y_1^{O_1} y_1^{O_2} \dots y_1^{O_L}$

• The objective of drawing: Produce the most likely output (that ends in an <eos>)

 $\operatorname*{argmax}_{o_1, \dots, o_L} y_1^{o_1} y_1^{o_2} \dots y_1^{o_L}$

Greedy drawing

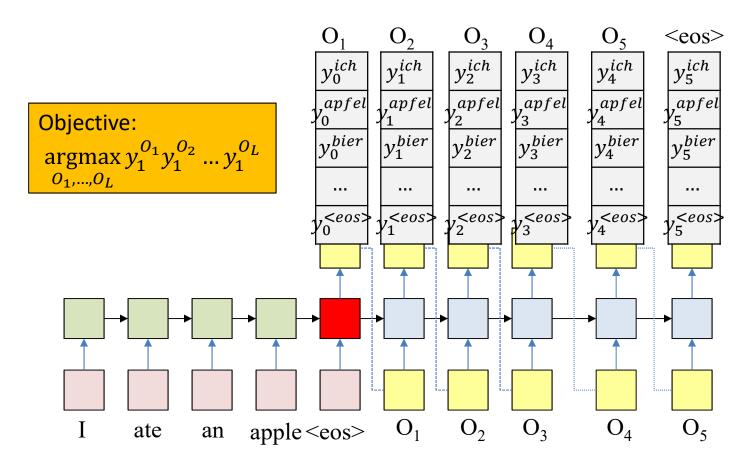

- So how do we draw words at each time to get the most likely word sequence?
- *Greedy* answer select the most probable word at each time

Pseudocode

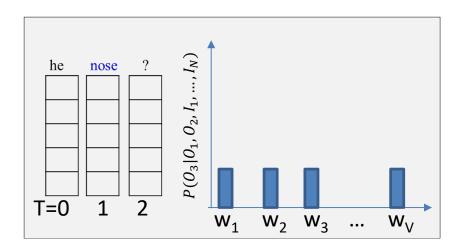

```
# First run the inputs through the network
# Assuming h(-1,1) is available for all layers
t = 0
do
     [h(t),..] = RNN input step(x(t),h(t-1),...)
until x(t) == "<eos>"
H = h(T-1)
# Now generate the output y_{out}(1), y_{out}(2),...
t = 0
\mathbf{h}_{out} (0) = \mathbf{H}
# Note: begins with a "start of sentence" symbol
#
        <sos> and <eos> may be identical
y_{out}(0) = \langle sos \rangle
do
    t = t+1
     [y(t), h_{out}(t)] = RNN_output_step(h_{out}(t-1), y_{out}(t-1))
     y_{out}(t) = argmax_i(y(t,i))
until y<sub>out</sub>(t) == <eos>
                                    Select the most likely output at each time
```

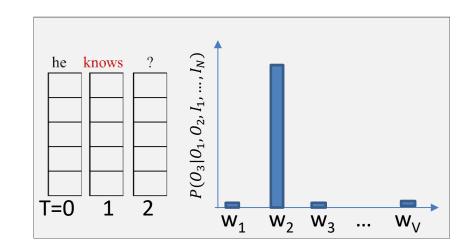

Greedy drawing

- Cannot just pick the most likely symbol at each time
 - That may cause the distribution to be more "confused" at the next time
 - Choosing a different, less likely word could cause the distribution at the next time to be more peaky, resulting in a more likely output overall

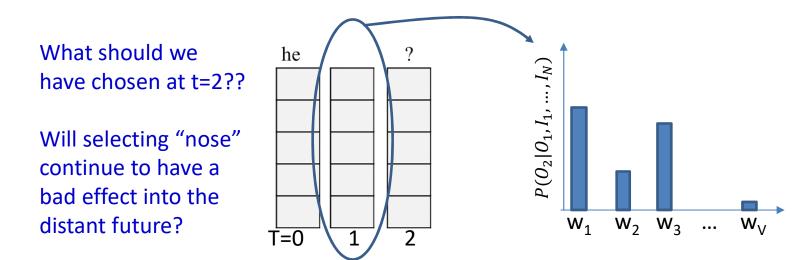

Greedy is not good

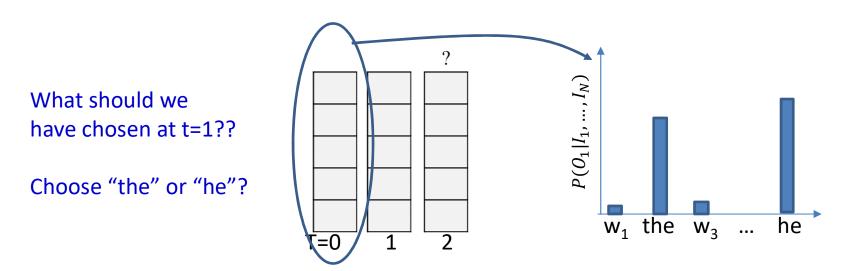

- Hypothetical example (from English speech recognition : Input is speech, output must be text)
- "Nose" has highest probability at t=2 and is selected
 - The model is very confused at t=3 and assigns low probabilities to many words at the next time
 - Selecting any of these will result in low probability for the entire 3-word sequence
- "Knows" has slightly lower probability than "nose", but is still high and is selected
 - "he knows" is a reasonable beginning and the model assigns high probabilities to words such as "something"
 - Selecting one of these results in higher overall probability for the 3-word sequence

Greedy is not good

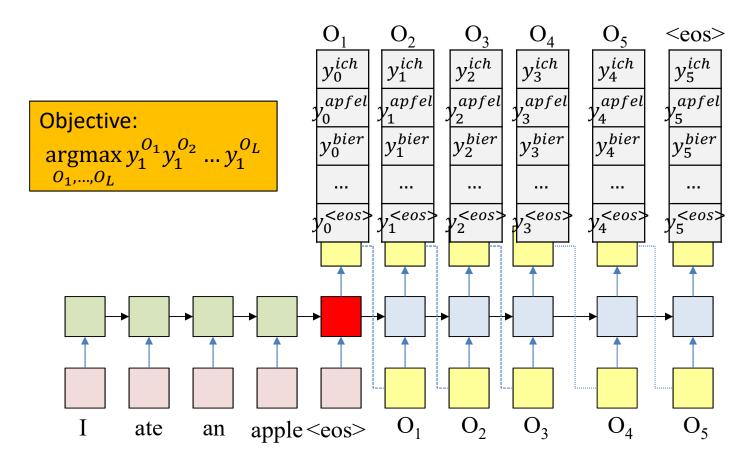

- Problem: Impossible to know a priori which word leads to the more promising future
 - Should we draw "nose" or "knows"?
 - Effect may not be obvious until several words down the line
 - Or the choice of the wrong word early may cumulatively lead to a poorer overall score over time

Greedy is not good

- Problem: Impossible to know a priori which word leads to the more promising future
 - Even earlier: Choosing the lower probability "the" instead of "he" at T=0 may have made a choice of "nose" more reasonable at T=1..
- In general, making a poor choice at any time commits us to a poor future
 - But we cannot know at that time the choice was poor
- Solution: Don't choose..

Drawing by random sampling

 Alternate option: Randomly draw a word at each time according to the output probability distribution

Pseudocode

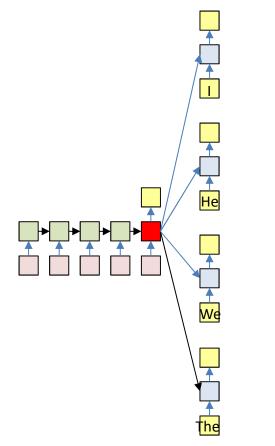

```
# First run the inputs through the network
# Assuming h(-1,1) is available for all layers
t = 0
do
     [h(t),..] = RNN input step(x(t),h(t-1),...)
until x(t) == "<eos>"
H = h(T-1)
# Now generate the output y_{out}(1), y_{out}(2),...
t = 0
\mathbf{h}_{out} (0) = \mathbf{H}
# Note: begins with a "start of sentence" symbol
#
        <sos> and <eos> may be identical
y_{out}(0) = \langle sos \rangle
do
    t = t+1
     [y(t), h_{out}(t)] = RNN_output_step(h_{out}(t-1), y_{out}(t-1))
     y_{out}(t) = sample(y(t))
until y<sub>out</sub>(t) == <eos>
                                   Randomly sample from the output distribution.
```

Drawing by random sampling

- Alternate option: Randomly draw a word at each time according to the output probability distribution
 - Unfortunately, not guaranteed to give you the most likely output
 - May sometimes give you more likely outputs than greedy drawing though

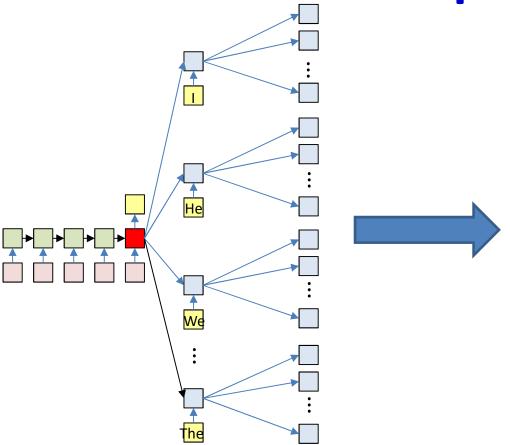

Optimal Solution: Multiple choices

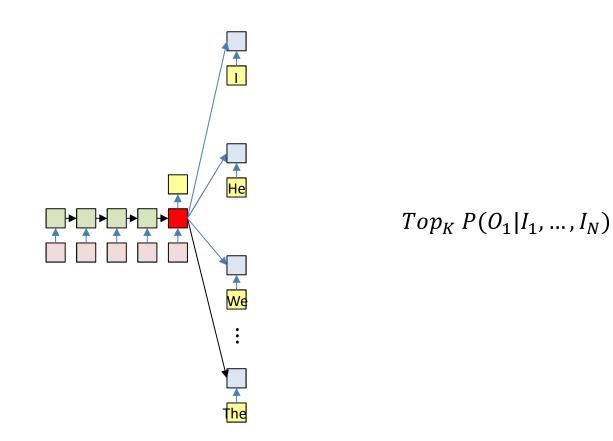

• Retain all choices and *fork* the network

- With every possible word as input

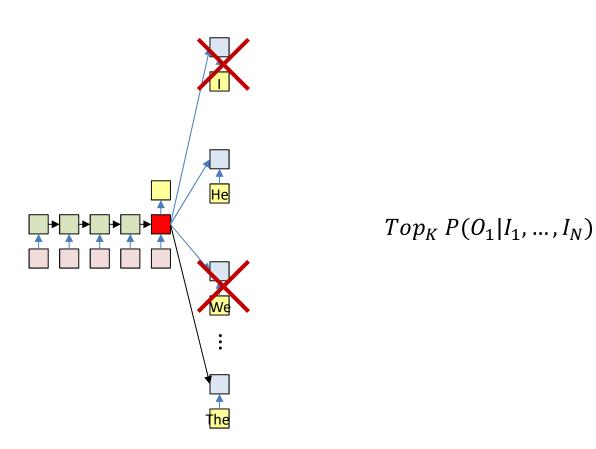

Problem: Multiple choices

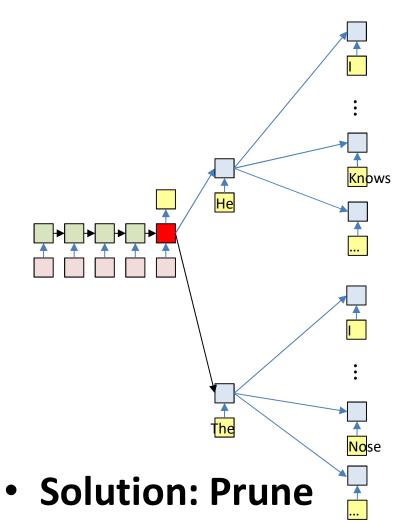

- Problem: This will blow up very quickly
 - For an output vocabulary of size V, after T output steps we'd have forked out V^T branches

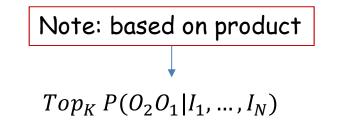

• Solution: Prune

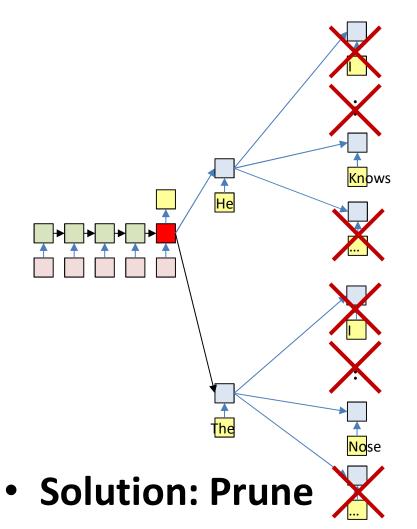

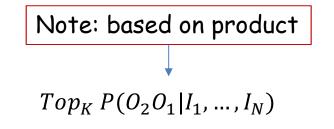

• Solution: Prune

 $= Top_{K} P(O_{2}|O_{1}, I_{1}, ..., I_{N}) P(O_{1}|I_{1}, ..., I_{N})$

 $= Top_{K} P(O_{2}|O_{1}, I_{1}, ..., I_{N}) P(O_{1}|I_{1}, ..., I_{N})$

 Or continue producing more outputs (each of which terminates in <eos>) to get N-best outputs

Termination: <eos>

- Paths cannot continue once the output an <eos>
 - So paths may be different lengths

۲

- Select the most likely sequence ending in <eos> across *all* terminating sequences

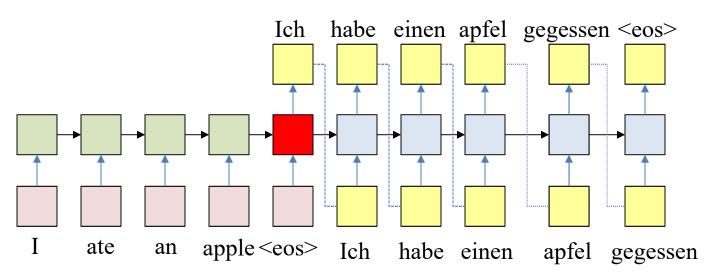

Pseudocode: Beam search

```
# Assuming encoder output H is available
path = \langle sos \rangle
beam = {path}
pathscore = [path] = 1
state[path] = h[0] # Output of encoder
do # Step forward
    nextbeam = \{\}
    nextpathscore = []
    nextstate = {}
    for path in beam:
        cfin = path[end]
        hpath = state[path]
        [y,h] = RNN output step(hpath,cfin)
        for c in Symbolset
            newpath = path + c
            nextstate[newpath] = h
            nextpathscore[newpath] = pathscore[path]*y[c]
            nextbeam += newpath # Set addition
        end
    end
    beam, pathscore, state, bestpath = prune(nextstate,nextpathscore,nextbeam,bw)
until bestpath[end] = <eos>
```

Pseudocode: Prune

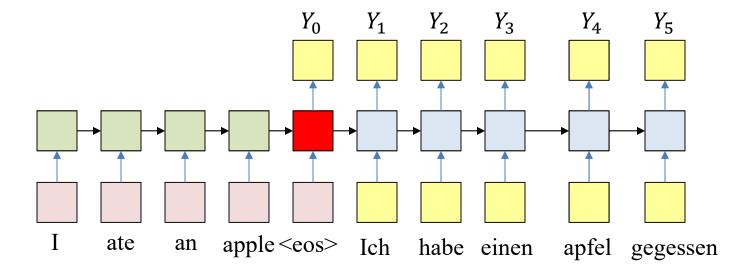

```
# Note, there are smarter ways to implement this
function prune (state, score, beam, beamwidth)
    sortedscore = sort(score)
    threshold = sortedscore[beamwidth]
   prunedstate = {}
   prunedscore = []
   prunedbeam = {}
    bestscore = -inf
   bestpath = none
    for path in beam:
        if score[path] > threshold:
            prunedbeam += path # set addition
            prunedstate[path] = state[path]
            prunedscore[path] = score[path]
            if score[path] > bestscore
                bestscore = score[path]
                bestpath = path
            end
        end
    end
    return prunedbeam, prunedscore, prunedstate, bestpath
```

Training the system

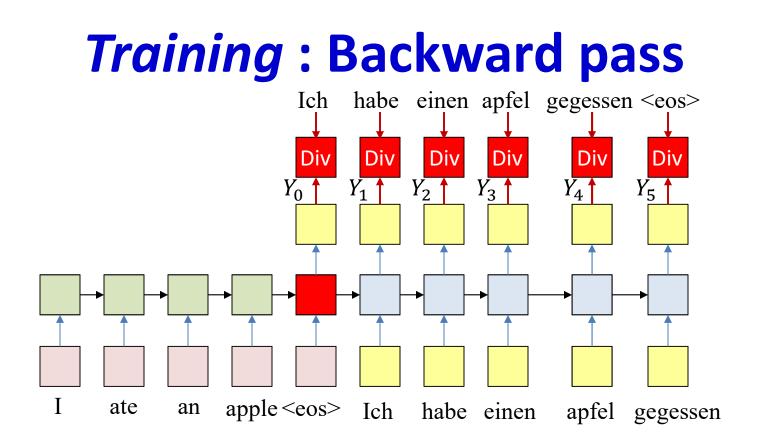

- Must learn to make predictions appropriately
 - Given "I ate an apple <eos>", produce "Ich habe einen apfel gegessen <eos>".

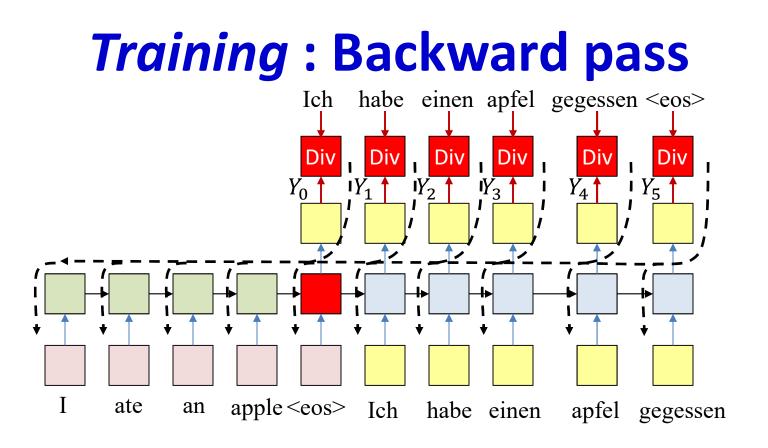

Training : Forward pass

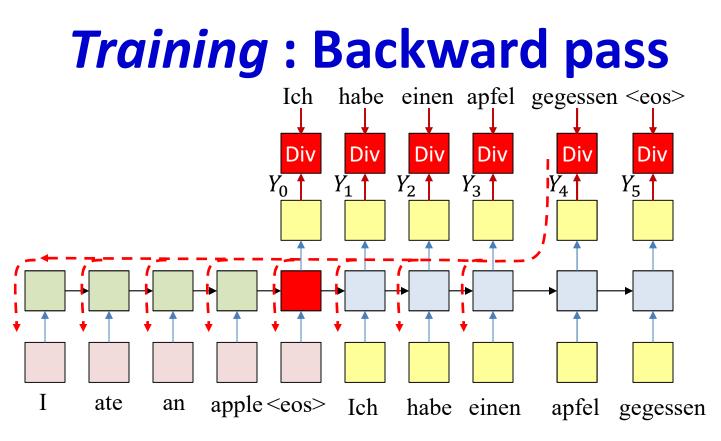

- Forward pass: Input the source and target sequences, sequentially
 - Output will be a probability distribution over target symbol set (vocabulary)

 Backward pass: Compute the divergence between the output distribution and target word sequence

- Backward pass: Compute the divergence between the output distribution and target word sequence
- Backpropagate the derivatives of the divergence through the network to learn the net

- In practice, if we apply SGD, we may randomly sample words from the output to actually use for the backprop and update
 - Typical usage: Randomly select one word from each input training instance (comprising an input-output pair)
 - For each iteration
 - Randomly select training instance: (input, output)
 - Forward pass
 - Randomly select a single output y(t) and corresponding desired output d(t) for backprop

Overall training

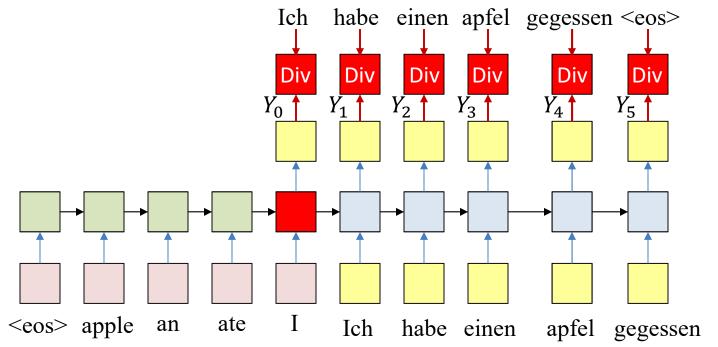

- Given several training instance (X, D)
- Forward pass: Compute the output of the network for (**X**, **D**)

- Note, both X and D are used in the forward pass

 Backward pass: Compute the divergence between the desired target **D** and the actual output **Y**

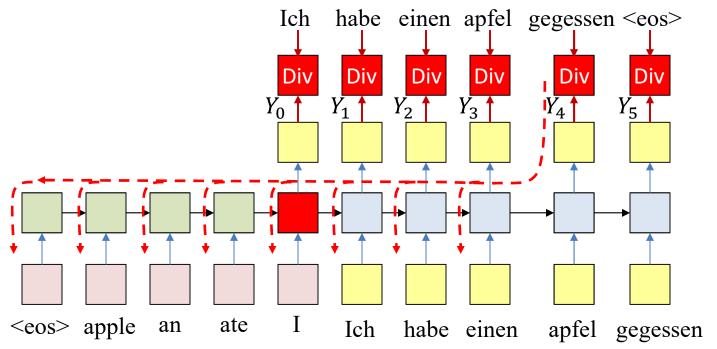

Propagate derivatives of divergence for updates

Trick of the trade: Reversing the input

- Standard trick of the trade: The input sequence is fed *in reverse order*
 - Things work better this way

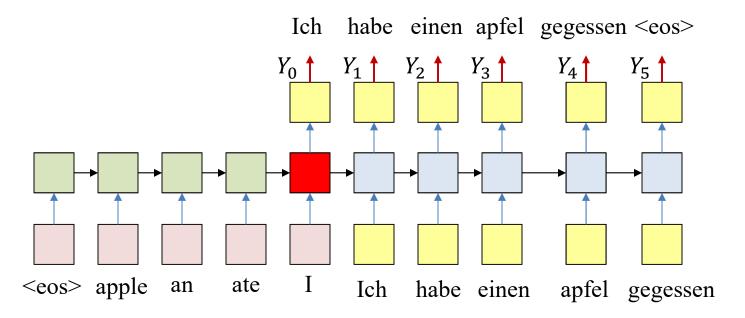

Trick of the trade: Reversing the input

• Standard trick of the trade: The input sequence is fed *in reverse order*

Things work better this way

Trick of the trade: Reversing the input

- Standard trick of the trade: The input sequence is fed in reverse order
 - Things work better this way
- This happens both for training and during actual decode

Overall training

- Given several training instance (X, D)
- Forward pass: Compute the output of the network for (X, D) with input in reverse order

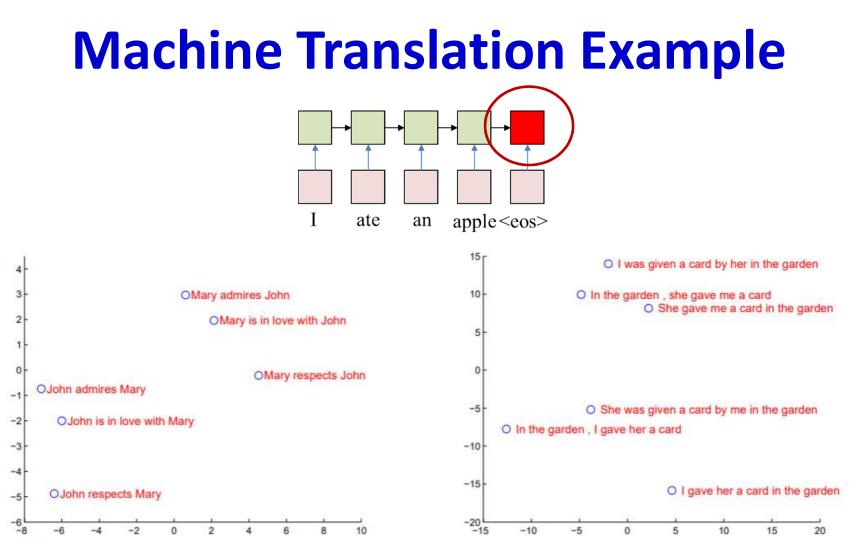

- Note, both X and D are used in the forward pass

 Backward pass: Compute the divergence between the desired target **D** and the actual output **Y**

Propagate derivatives of divergence for updates

Applications

- Machine Translation
 - My name is Tom → Ich heisse Tom/Mein name ist Tom
- Automatic speech recognition
 - Speech recording \rightarrow "My name is Tom"
- Dialog
 - "I have a problem" \rightarrow "How may I help you"
- Image to text
 - Picture \rightarrow Caption for picture

- Hidden state clusters by meaning!

- Task: Human text in, machine response out

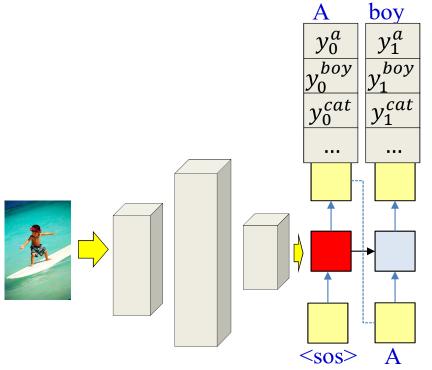

- Not really a seq-to-seq problem, more an image-to-sequence problem
- Initial state is produced by a state-of-art CNN-based image classification system
 - Subsequent model is just the decoder end of a seq-to-seq model
 - "Show and Tell: A Neural Image Caption Generator", O. Vinyals, A. Toshev, S. Bengio, D. Erhan

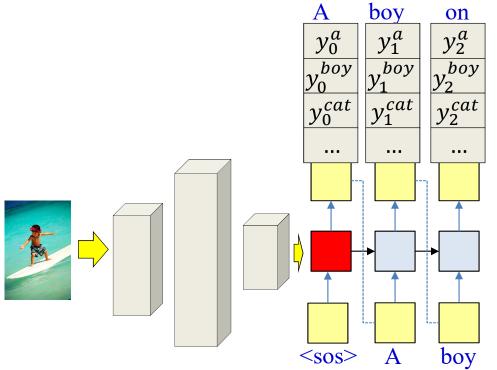

- Decoding: Given image
 - Process it with CNN to get output of classification layer

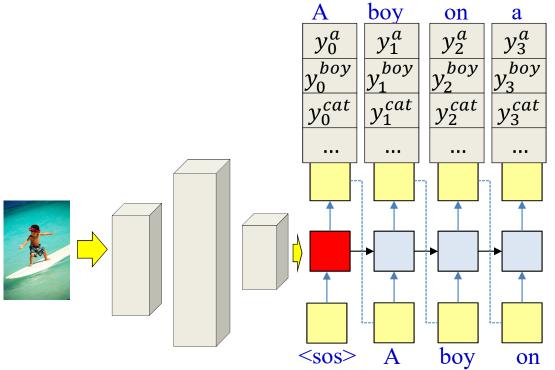

- Decoding: Given image
 - Process it with CNN to get output of classification layer
 - Sequentially generate words by drawing from the conditional output distribution $P(W_t|W_0W_1 \dots W_{t-1}, Image)$
 - In practice, we can perform the beam search explained earlier

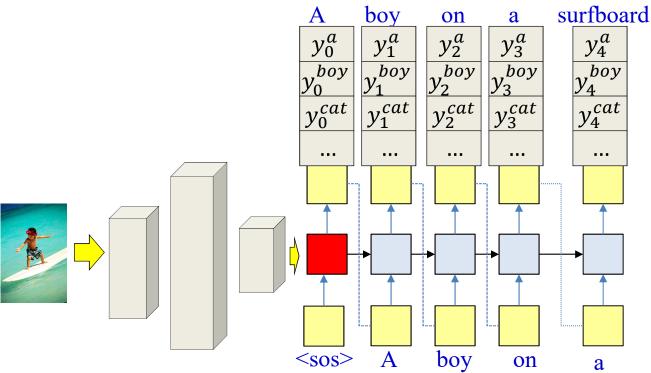

- Decoding: Given image
 - Process it with CNN to get output of classification layer
 - Sequentially generate words by drawing from the conditional output distribution $P(W_t|W_0W_1 \dots W_{t-1}, Image)$
 - In practice, we can perform the beam search explained earlier

Training

- **Training**: Given several (Image, Caption) pairs
 - The image network is pretrained on a large corpus, e.g. image net

- Training: Given several (Image, Caption) pairs
 - The image network is pretrained on a large corpus, e.g. image net
- Forward pass: Produce output distributions given the image and caption

- Training: Given several (Image, Caption) pairs
 - The image network is pretrained on a large corpus, e.g. image net
- Forward pass: Produce output distributions given the image and caption
- **Backward pass:** Compute the divergence w.r.t. training caption, and backpropagate derivatives
 - All components of the network, including final classification layer of the image classification net are updated
 - The CNN portions of the image classifier are not modified (transfer learning)

Examples from Vinyals et. Al.

"man in black shirt is playing guitar."

"construction worker in orange safety vest is working on road."

"two young girls are playing with lego toy."

"boy is doing backflip on wakeboard."

"a young boy is holding a baseball bat."

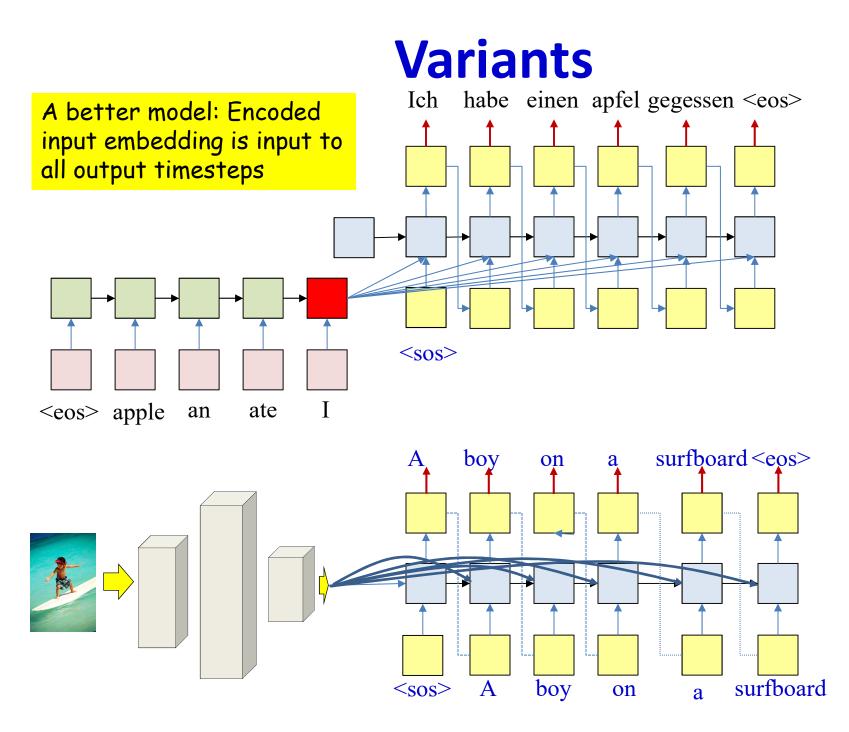

"a cat is sitting on a couch with a remote control."

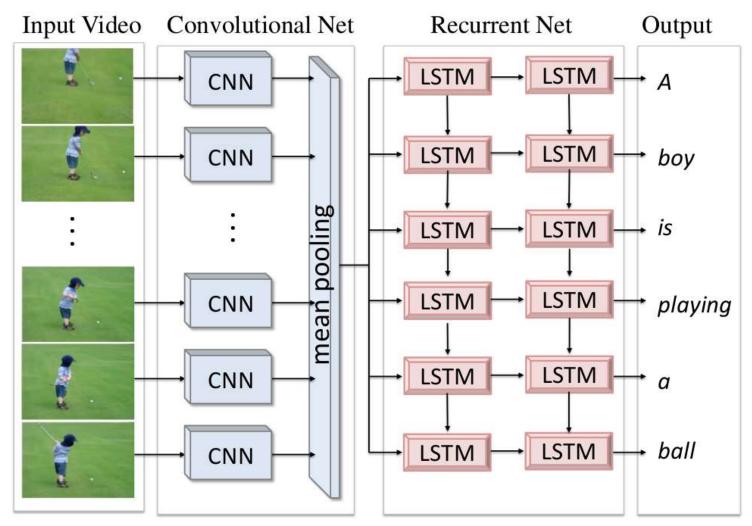

"a woman holding a teddy bear in front of a mirror."

"a horse is standing in the middle of a road." 96

Translating Videos to Natural Language Using Deep Recurrent Neural Networks

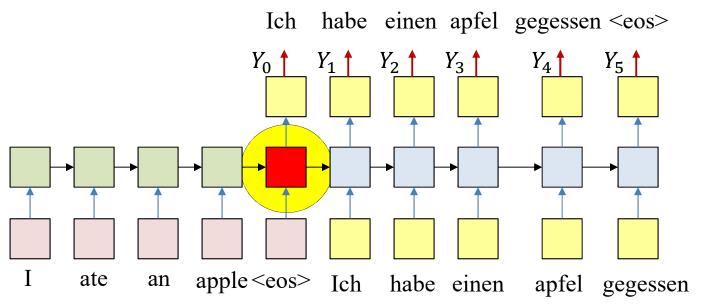

Translating Videos to Natural Language Using Deep Recurrent Neural Networks Subhashini Venugopalan, Huijun Xu, Jeff Donahue, Marcus Rohrbach, Raymond Mooney, Kate Saenko North American Chapter of the Association for Computational Linguistics, Denver, Colorado, June 2015.

Pseudocode

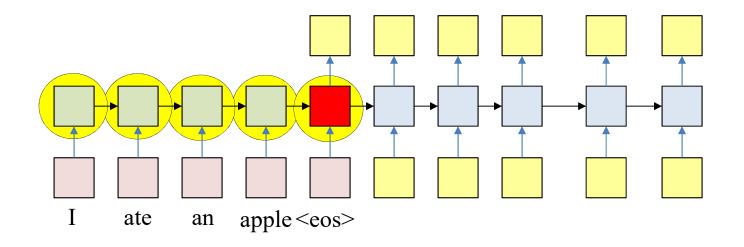

```
# Assuming encoded input H (from text, image, video)
# is available
# Now generate the output y_{out}(1), y_{out}(2),...
t = 0
\mathbf{h}_{out}(0) = \mathbf{H} # Encoder embedding
# Note: begins with a "start of sentence" symbol
#
        <sos> and <eos> may be identical
y_{out}(0) = \langle sos \rangle
do
    t = t+1
     [y(t), h_{out}(t)] = RNN_output_step(h_{out}(t-1), y_{out}(t-1), H)
     y_{out}(t) = generate(y(t)) # Beam search, random, or greedy
until y_{out}(t) == \langle eos \rangle
```

until y<sub>out</sub>(t) == <eos>
```

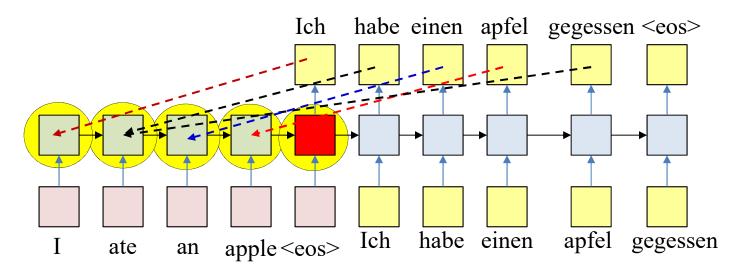

- All the information about the input sequence is embedded into a *single* vector
 - The "hidden" node layer at the end of the input sequence
 - This one node is "overloaded" with information
 - Particularly if the input is long

• In reality: All hidden values carry information

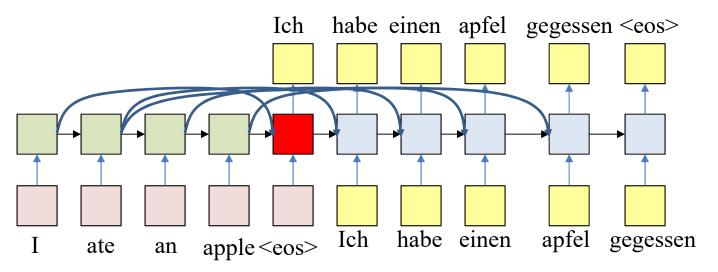

- Some of which may be diluted downstream

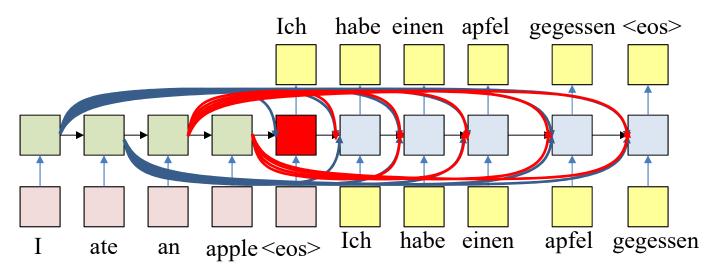

• In reality: All hidden values carry information

- Some of which may be diluted downstream

- Different outputs are related to different inputs
 - Recall input and output may not be in sequence

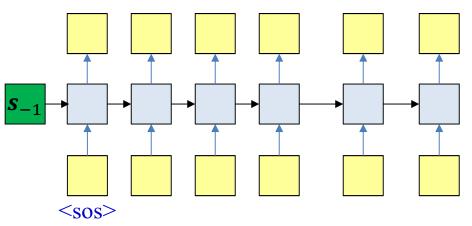

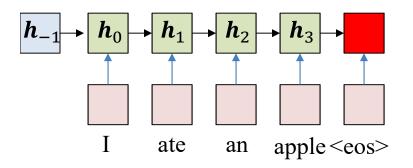

- In reality: *All* hidden values carry information
 - Some of which may be diluted downstream
- Different outputs are related to different inputs
 - Recall input and output may not be in sequence
 - Have no way of knowing a priori which input must connect to what output

- In reality: All hidden values carry information
 - Some of which may be diluted downstream
- Different outputs are related to different inputs
 - Recall input and output may not be in sequence
 - Have no way of knowing a priori which input must connect to what output
- Connecting everything to everything is infeasible
 - Variable sized inputs and outputs
 - Overparametrized
 - Connection pattern ignores the actual asynchronous dependence of output on input
 105

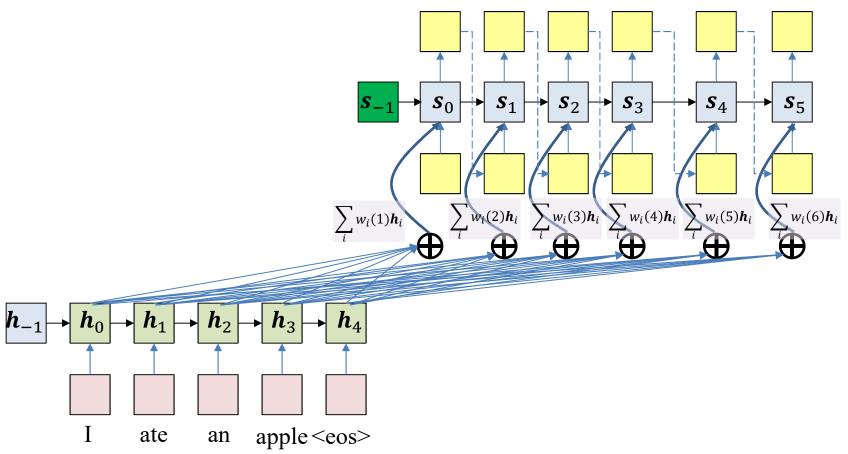

Solution: Attention models

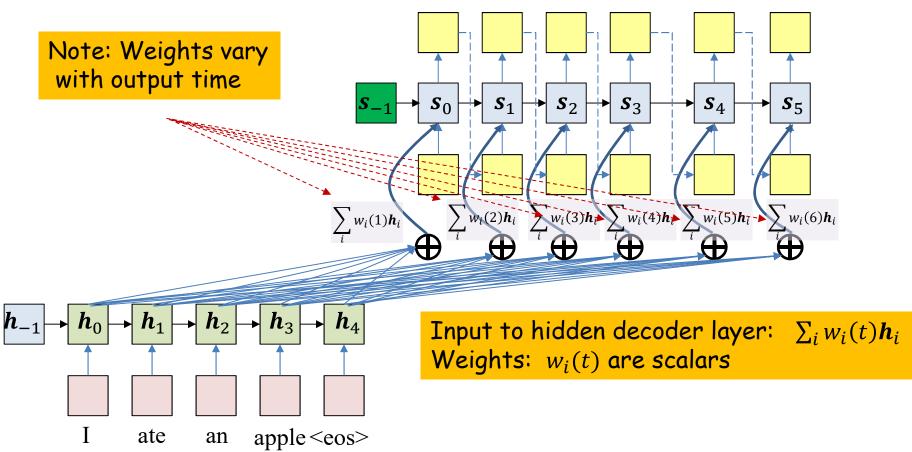

• Separating the encoder and decoder in illustration

Solution: Attention models

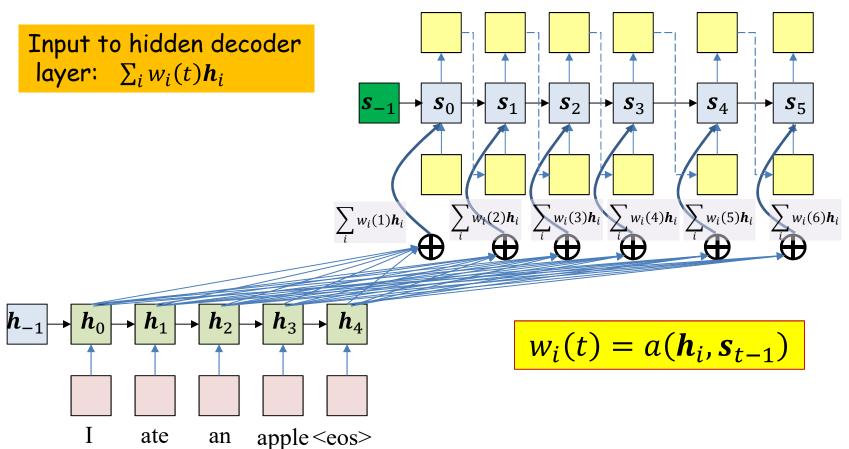

- Compute a weighted combination of all the hidden outputs into a single vector
 - Weights vary by output time

Solution: Attention models

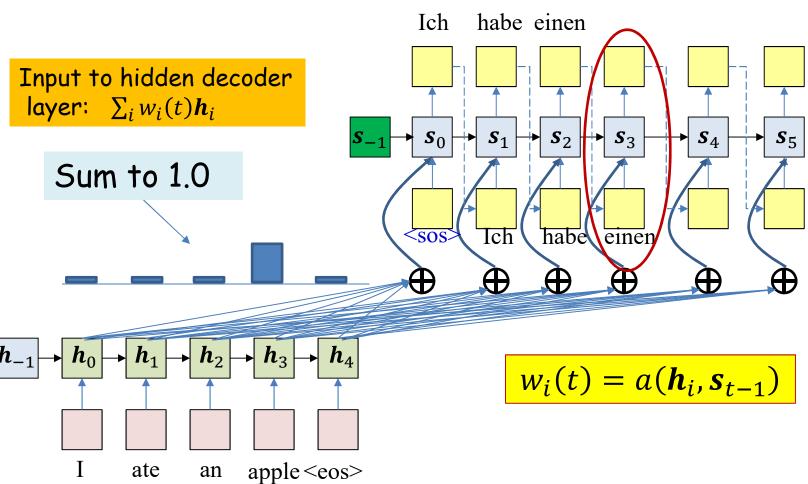

- Compute a weighted combination of all the hidden outputs into a single vector
 - Weights vary by output time

Solution: Attention models

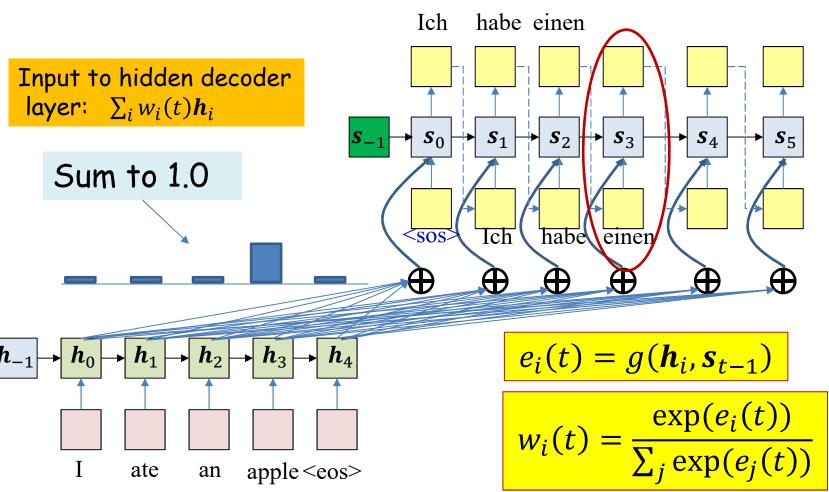

- Require a time-varying weight that specifies relationship of output time to input time
 - Weights are *functions* of current output state

Attention models

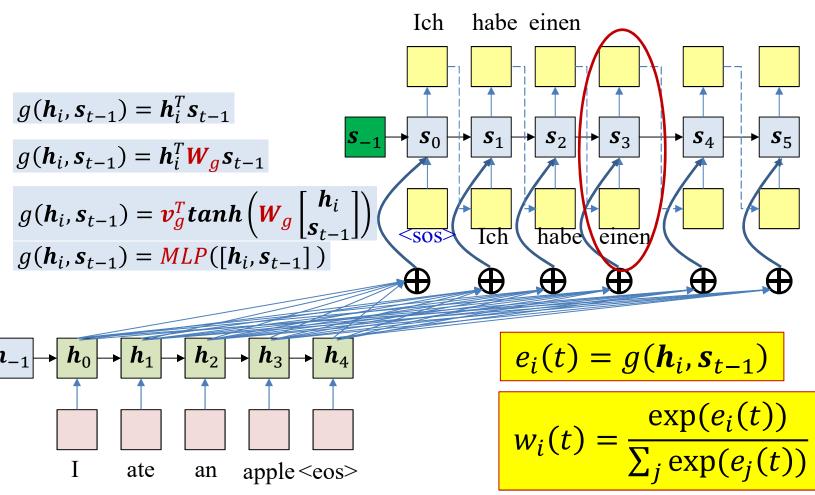

- The weights are a distribution over the input
 - Must automatically highlight the most important input components for any output

Attention models

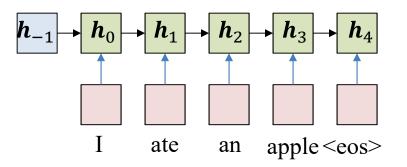

- "Raw" weight at any time: A function g() that works on the two hidden states
- Actual weight: softmax over raw weights

Attention models

• Typical options for g()...

- Variables in red are to be learned

• Pass the input through the encoder to produce hidden representations h_i

What is this? Multiple options

h.

Ι

ate

Simplest: $s_{-1} = h_N$ If s and h are different sizes: $s_{-1} = W_s h_N$ W_s is learnable parameter

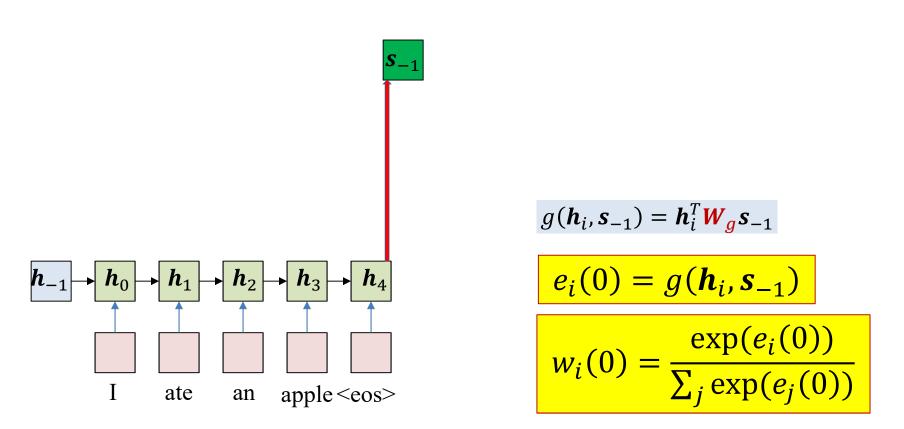

• Compute weights for first output

 h_3

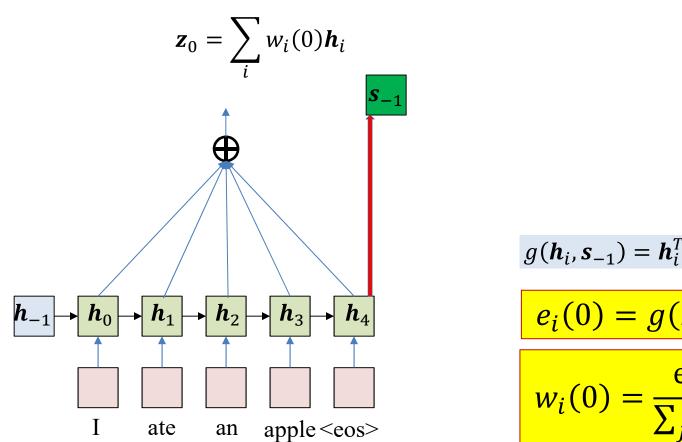

apple <eos>

 \boldsymbol{n}_2

an

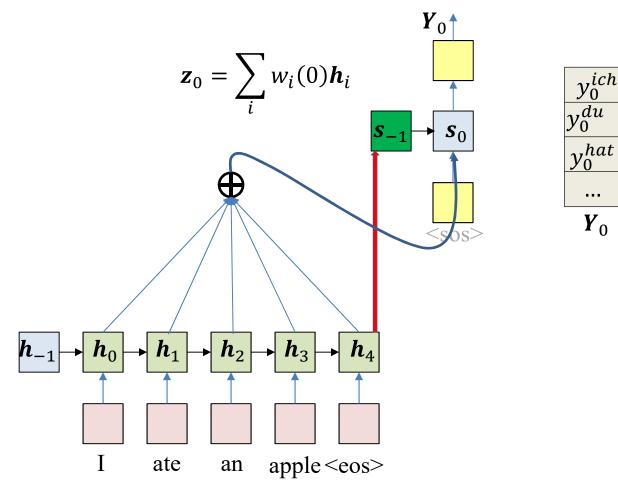

• Compute weights (for every $oldsymbol{h}_i$) for first output

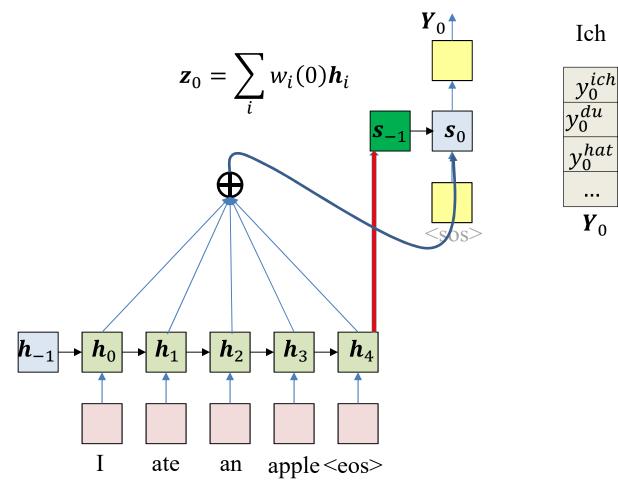

$$g(\mathbf{h}_i, \mathbf{s}_{-1}) = \mathbf{h}_i^T \mathbf{W}_g \mathbf{s}_{-1}$$
$$e_i(0) = g(\mathbf{h}_i, \mathbf{s}_{-1})$$
$$w_i(0) = \frac{\exp(e_i(0))}{\sum_j \exp(e_j(0))}$$

- Compute weights (for every $oldsymbol{h}_i$) for first output
- Compute weighted combination of hidden values

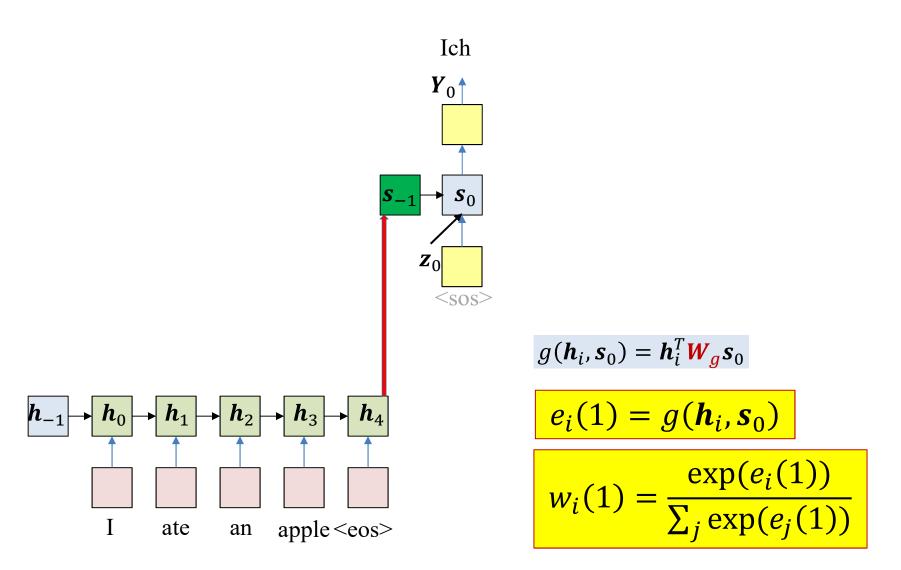

• Produce the first output

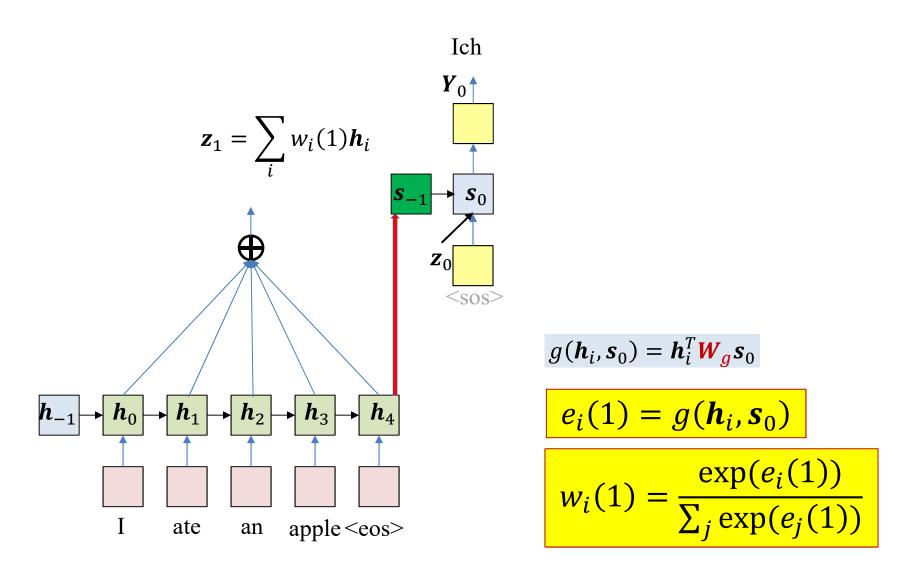

- Will be distribution over words

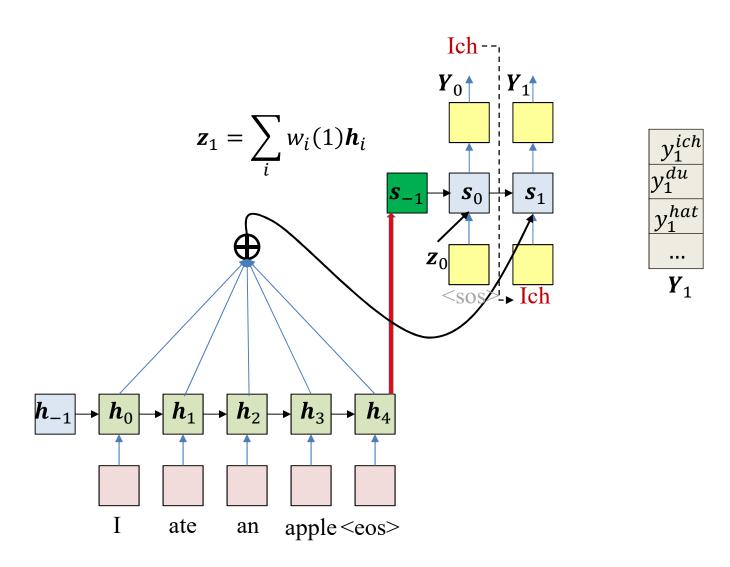

- Produce the first output
 - Will be distribution over words
 - Draw a word from the distribution

 Compute the weights for all instances for time = 1

 Compute the weighted sum of hidden input values at t=1

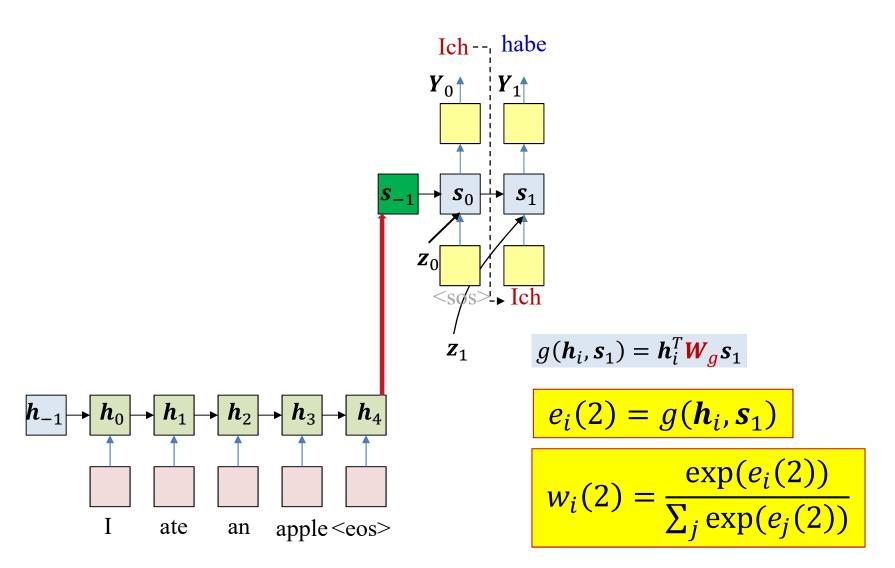

• Compute the output at t=1

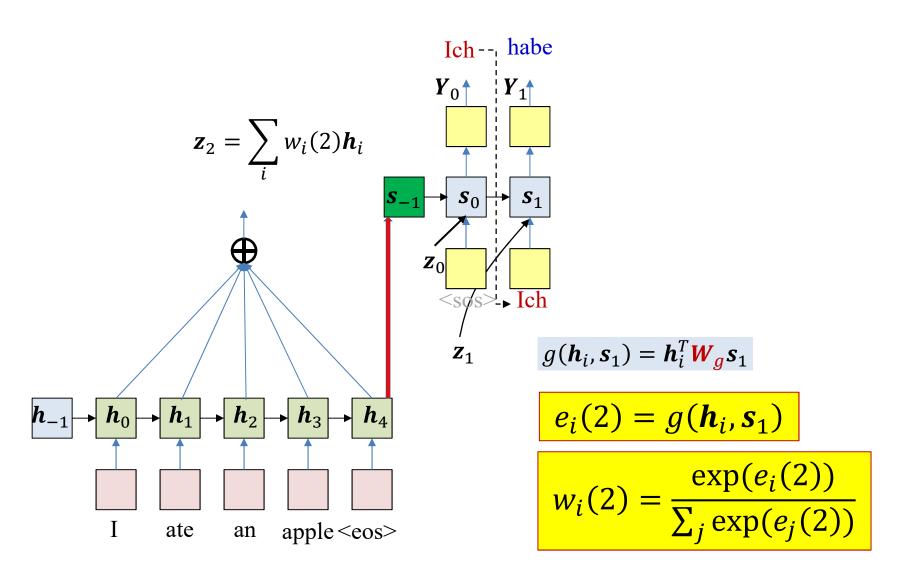

– Will be a probability distribution over words

 Draw a word from the output distribution at t=1

 Compute the weights for all instances for time = 2

 Compute the weighted sum of hidden input values at t=2

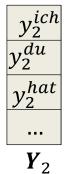

• Compute the output at t=2

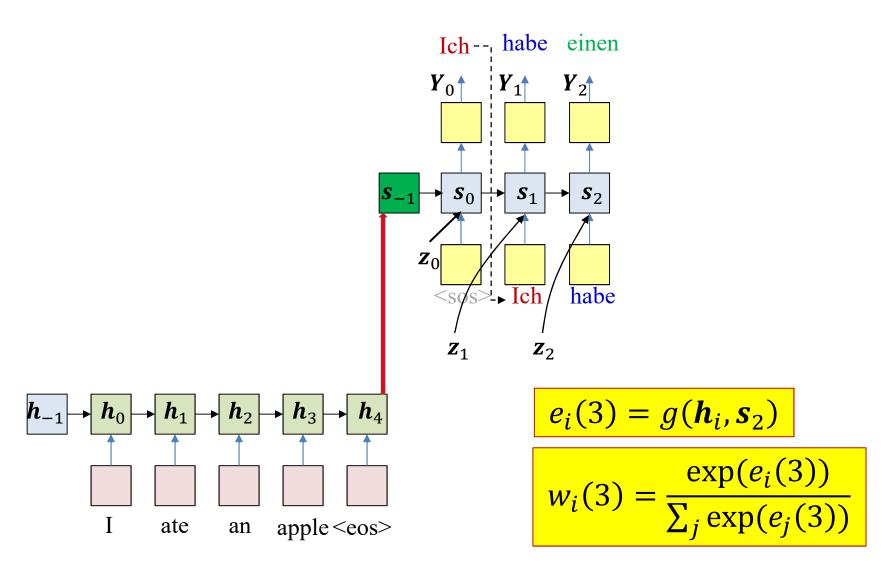

– Will be a probability distribution over words

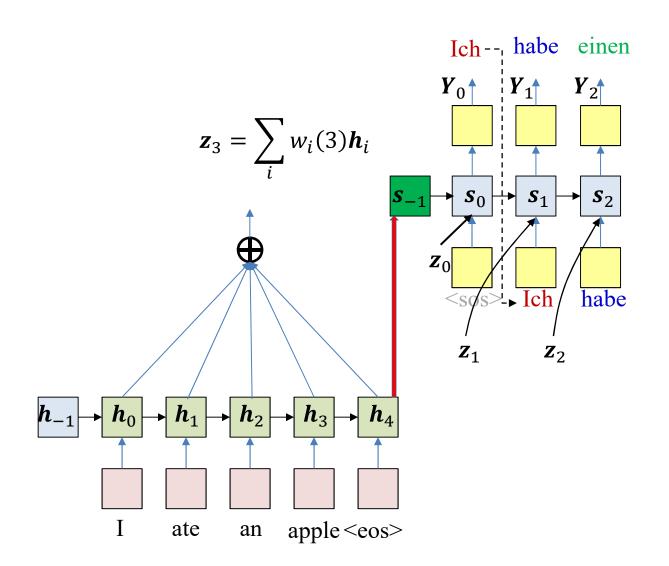

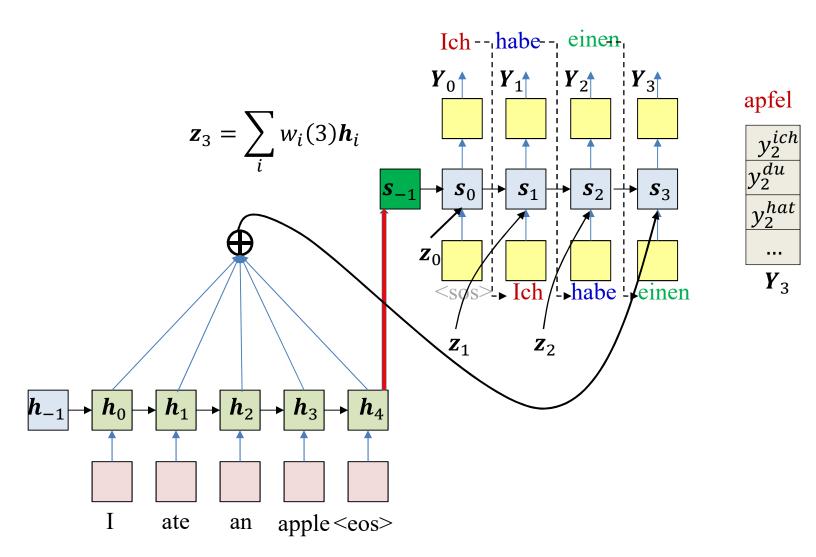

Draw a word from the distribution

 Compute the weights for all instances for time = 3

 Compute the weighted sum of hidden input values at t=3

- Compute the output at t=3
 - Will be a probability distribution over words
 - Draw a word from the distribution

 Continue the process until an end-of-sequence symbol is produced

Pseudocode

Assuming encoded input $H = [h_{enc}[0] \dots h_{enc}[T]]$ is available

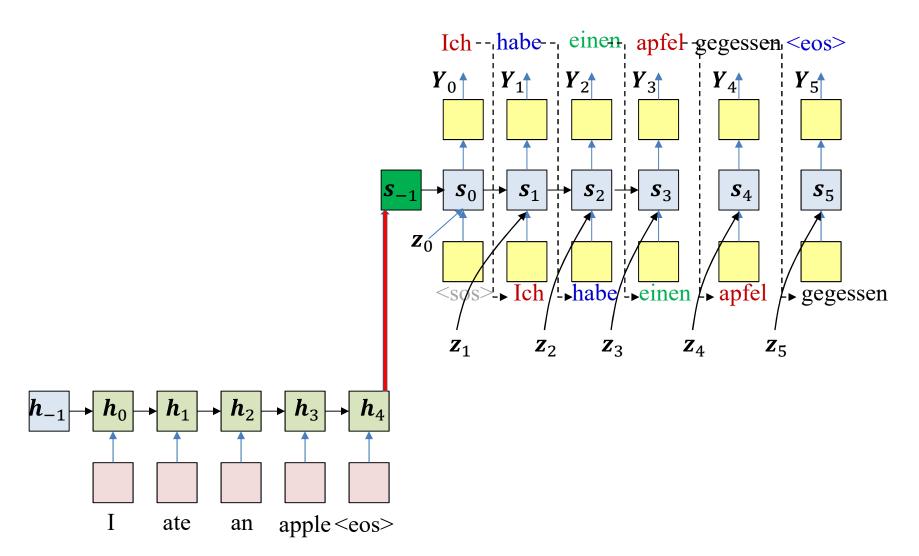

```
t = 0
h<sub>out</sub>[-1] = 0 # Initial Decoder hidden state
# Note: begins with a "start of sentence" symbol
# <sos> and <eos> may be identical
Y<sub>out</sub>[0] = <sos>
do
        t = t+1
        C = compute_context_with_attention(h<sub>out</sub>[t-1], H)
        y[t], h<sub>out</sub>[t] = RNN_decode_step(h<sub>out</sub>[t-1], Y<sub>out</sub>[t-1], C)
        y<sub>out</sub>[t] = generate(y[t]) # Random, or greedy
until y<sub>out</sub>[t] == <eos>
```

Pseudocode : Computing context with attention

Takes in previous state, encoder states, outputs attention-weighted context function compute context with attention(h, x, H)

```
# First compute attention
e = []
for t = 1:T # Length of input
    e[t] = raw_attention(h, H[t])
end
maxe = max(e) # subtract max(e) from everything to prevent underflow
a[1..T] = exp(e[1..T] - maxe) # Component-wise exponentiation
suma = sum(a) # Add all elements of a
a[1..T] = a[1..T]/suma
C = 0
for t = 1..T
    C += a[t] * H[t]
end
```

return **C**

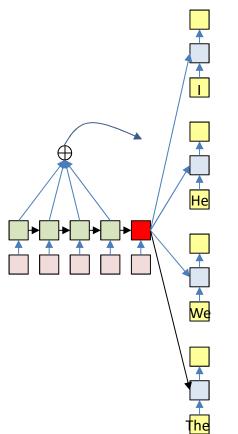

• As before, the objective of drawing: Produce the most likely output (that ends in an <eos>)

$$\operatorname*{argmax}_{O_1,\dots,O_L} y_1^{O_1} y_1^{O_2} \dots y_1^{O_L}$$

• Simply selecting the most likely symbol at each time may result in suboptimal output

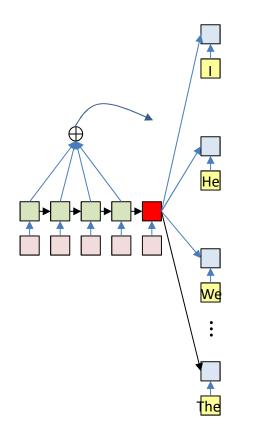

Solution: Multiple choices

• Retain all choices and *fork* the network

- With every possible word as input

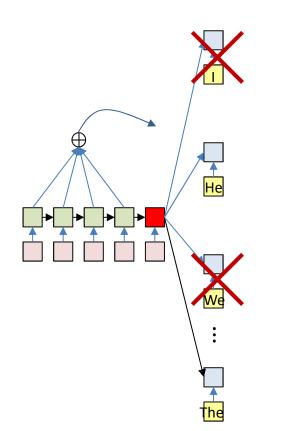

To prevent blowup: Prune

 $Top_K P(O_1|I_1,\ldots,I_N)$

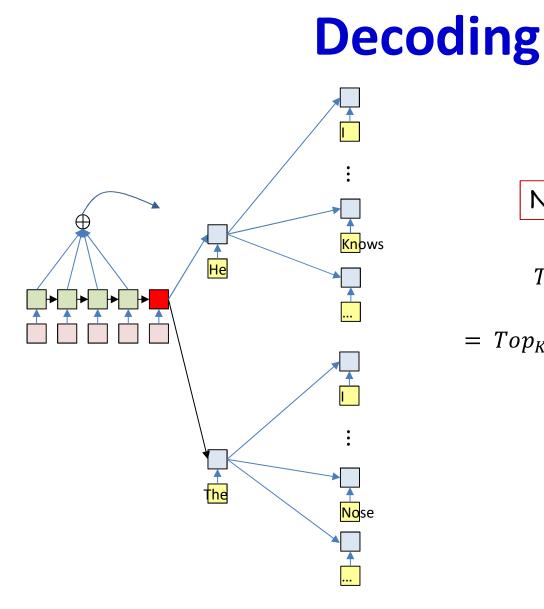

• Prune

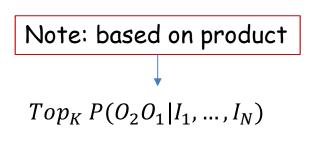

To prevent blowup: Prune

 $Top_K P(O_1|I_1,\ldots,I_N)$

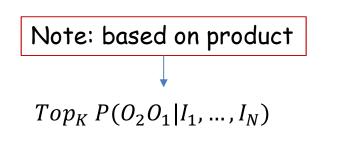

• Prune

 $= Top_{K} P(O_{2}|O_{1}, I_{1}, ..., I_{N}) P(O_{1}|I_{1}, ..., I_{N})$

 $= Top_{K} P(O_{2}|O_{1}, I_{1}, ..., I_{N}) P(O_{1}|I_{1}, ..., I_{N})$

 Or continue producing more outputs (each of which terminates in <eos>) to get N-best outputs

Termination: <eos>

- Paths cannot continue once the output an <eos>
 - So paths may be different lengths

۲

Select the most likely sequence ending in <eos> across all terminating sequences

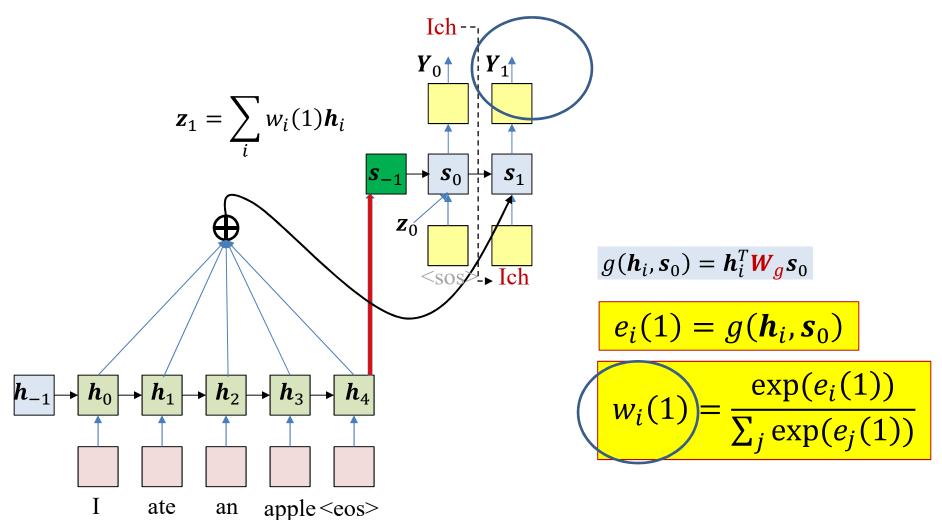

Pseudocode: Beam search

```
# Assuming encoder output H = h_{in}[1] \dots h_{in}[T] is available
path = <sos>
beam = \{path\}
pathscore = [path] = 1
state[path] = h[0] # initial state (computed using your favorite method)
do # Step forward
    nextbeam = \{\}
    nextpathscore = []
    nextstate = {}
    for path in beam:
        cfin = path[end]
        hpath = state[path]
        C = compute context with attention(hpath, H)
        y, h = RNN decode step(hpath, cfin, C)
        for c in Symbolset
            newpath = path + c
            nextstate[newpath] = h
            nextpathscore[newpath] = pathscore[path]*y[c]
            nextbeam += newpath # Set addition
        end
    end
    beam, pathscore, state, bestpath = prune(nextstate,nextpathscore,nextbeam)
until bestpath[end] = <eos>
```

Pseudocode: Beam search

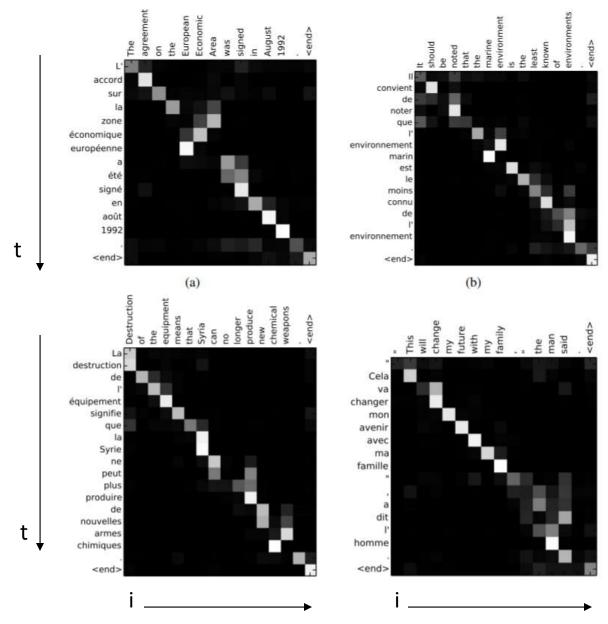

```
# Assuming encoder output H = h_{in}[1] \dots h_{in}[T] is available
path = \langle sos \rangle
beam = {path}
pathscore = [path] = 1
state[path] = h[0] # computed using your favorite method
context[path] = compute context with attention(h[0], H)
do # Step forward
                                                     Slightly more efficient.
    nextbeam = \{\}
    nextpathscore = []
    nextstate = {}
                                                     Does not perform redundant
    nextcontext = {}
    for path in beam:
                                                     context computation
        cfin = path[end]
        hpath = state[path]
        C = context[path]
        y, h = RNN decode step(hpath, cfin, C)
        nextC = compute context with attention(h, H)
        for c in Symbolset
            newpath = path + c
            nextstate[newpath] = h
            nextcontext[newpath] = nextC
            nextpathscore[newpath] = pathscore[path]*y[c]
            nextbeam += newpath # Set addition
        end
    end
    beam, pathscore, state, context, bestpath =
                          prune (nextstate, nextpathscore, nextbeam, nextcontext)
until bestpath[end] = <eos>
```

What does the attention learn?

- The key component of this model is the attention weight ullet
 - It captures the relative importance of each position in the input to the current output

"Alignments" example: Bahdanau et al.

Plot of $w_i(t)$ Color shows value (white is larger)

Note how most important input words for any output word get automatically highlighted

The general trend is somewhat linear because word order is roughly similar in both languages

• Bahdanau et al. 2016

Training the network

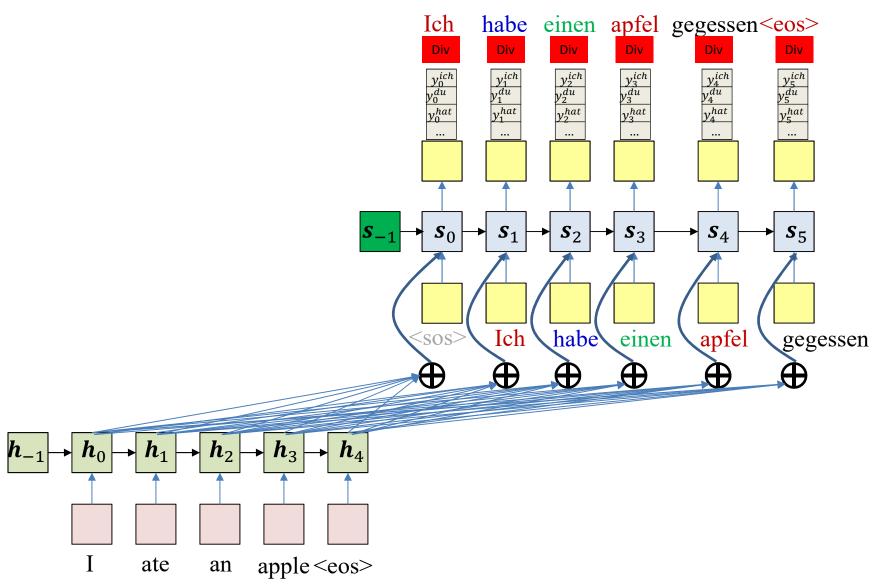

• We have seen how a trained network can be used to compute outputs

Convert one sequence to another

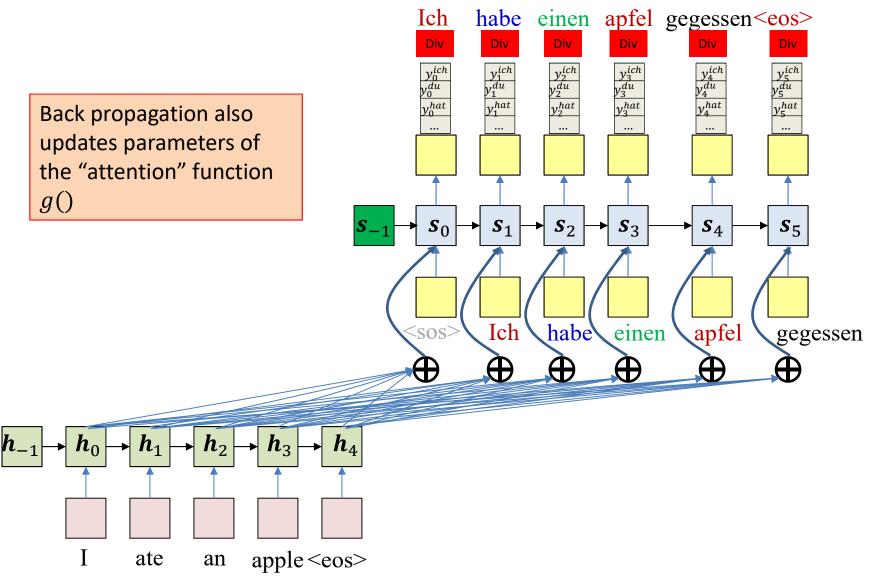

• Lets consider training..

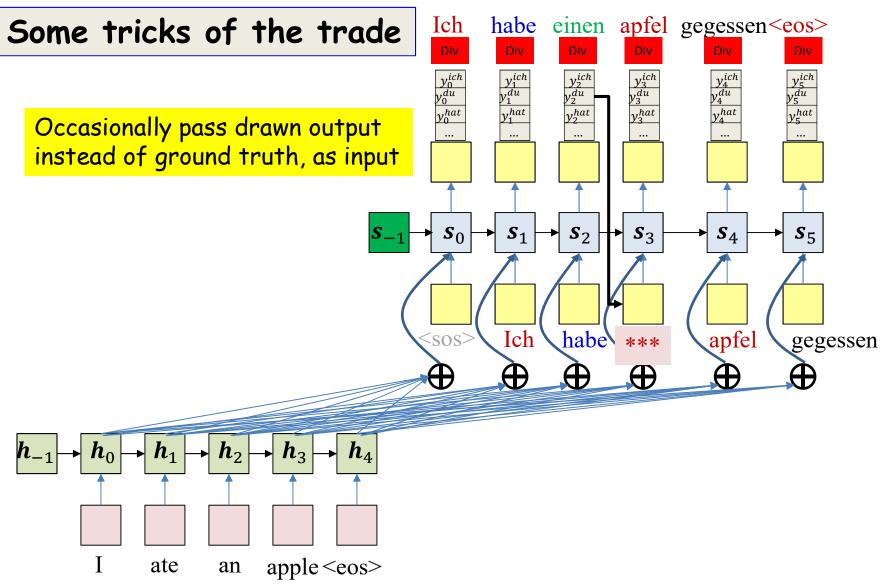

- Given training input (source sequence, target sequence) pairs
- Forward pass: Pass the actual Pass the input sequence through the encoder
 - At each time the output is a probability distribution over words

- **Backward pass**: Compute a divergence between target output and output distributions
 - Backpropagate derivatives through the network

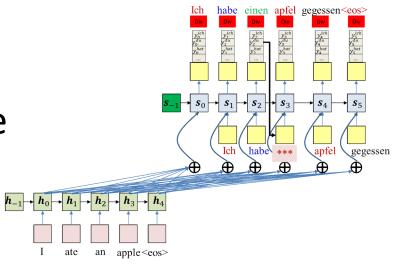

- **Backward pass**: Compute a divergence between target output and output distributions
 - Backpropagate derivatives through the network

- **Backward pass**: Compute a divergence between target output and output distributions
 - Backpropagate derivatives through the network

Tricks of the trade...

Teacher forcing:
 Occasionally pass the system output as input during training

• The "Gumbel noise" trick: Making drawing from a distribution differentiable

Various extensions

- Bidirectional processing of input sequence
 - Bidirectional networks in encoder
 - E.g. "Neural Machine Translation by Jointly Learning to Align and Translate", Bahdanau et al. 2016
- Attention: Local attention vs global attention
 - E.g. "Effective Approaches to Attention-based Neural Machine Translation", Luong et al., 2015
 - Other variants

Various extensions

- Multihead attention
 - Derive "value", and multiple "keys" from the encoder
 - $V_i, K_i^l, i = 1 \dots T, l = 1 \dots N_{head}$
 - Derive one or more "queries" from decoder
 - $Q_{j}^{l}, j = 1 \dots M, l = 1 \dots N_{head}$
 - Each query-key pair gives you one attention distribution
 - And one context vector
 - $a_{j,i}^l = attention(Q_j^l, K_i^l, i = 1 \dots T), \quad C_j^l = \sum_i a_{j,i}^l V_i$
 - Concatenate set of context vectors into one extended context vector
 - $C_j = [C_j^1 \ C_j^2 \dots C_j^{N_{head}}]$
- Each "attender" focuses on a different aspect of the input that's important for the decode

Some impressive results..

- Attention-based models are currently responsible for the state of the art in many sequence-conversion systems
 - Machine translation
 - Input: Speech in source language
 - Output: Speech in target language
 - Speech recognition
 - Input: Speech audio feature vector sequence
 - Output: Transcribed word or character sequence

Attention models in image captioning

A woman is throwing a frisbee in a park.

A dog is standing on a hardwood floor.

A <u>stop</u> sign is on a road with a mountain in the background.

A little girl sitting on a bed with a teddy bear.

A group of <u>people</u> sitting on a boat in the water.

A giraffe standing in a forest with trees in the background.

- "Show attend and tell: Neural image caption generation with visual attention", Xu et al., 2016
- Encoder network is a convolutional neural network
 - Filter outputs at each location are the equivalent of h_i in the regular sequence-to-sequence model

In closing

- Have looked at various forms of sequence-to-sequence models
- Generalizations of recurrent neural network formalisms
- For more details, please refer to papers
 - Post on piazza if you have questions
- Will appear in HW4: Speech recognition with attention models
