Front Matter

- Announcements:
 - None!
- Recommended Readings:
 - Murphy, Chapters 8.1-8.3

Recall: Probabilistic Learning

- Previously:
 - (Unknown) Target function, $c^* : \mathcal{X} \rightarrow \mathcal{Y}$
 - Classifier, $h : \mathcal{X} \rightarrow \mathcal{Y}$
 - Goal: find a classifier, h , that best approximates c^*
- Now:
 - (Unknown) Target distribution, $y \sim P^*(Y|\mathbf{x})$
 - Distribution, $P(Y|\mathbf{x})$
 - Goal: find a distribution, P , that best approximates P^*

Building a Probabilistic Classifier

- Define a decision rule
 - Given a test data point \mathbf{x}' , predict its label \hat{y} using the *posterior distribution* $P(Y = y|X = \mathbf{x}')$
 - Common choice: $\hat{y} = \operatorname{argmax}_y P(Y = y|X = \mathbf{x}')$
- Model the posterior distribution
 - Option 1 - Model $P(Y|X)$ directly as some function of X (today!)
 - Option 2 - Use Bayes' rule (later):

$$P(Y|X) = \frac{P(X|Y) P(Y)}{P(X)} \propto P(X|Y) P(Y)$$

Modelling the Posterior

- Suppose we have binary labels $y \in \{0,1\}$ and D -dimensional inputs $\mathbf{x} = [1, x_1, \dots, x_D]^T \in \mathbb{R}^{D+1}$
- Assume

$$P(Y = 1|\mathbf{x}) = \text{logit}(\mathbf{w}^T \mathbf{x}) = \frac{1}{1 + \exp(-\mathbf{w}^T \mathbf{x})}$$

$$= \frac{\exp(\mathbf{w}^T \mathbf{x})}{\exp(\mathbf{w}^T \mathbf{x}) + 1}$$

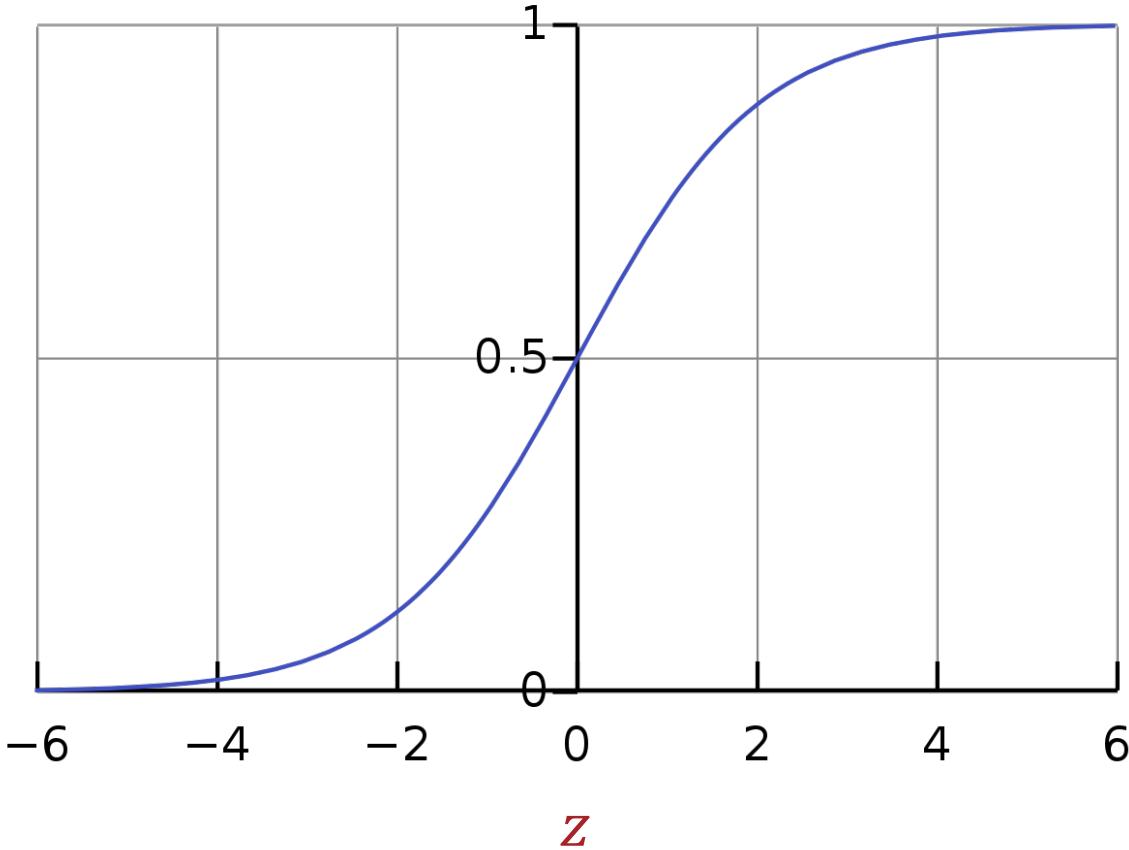

- This implies two useful facts:

1. $P(Y = 0|\mathbf{x}) = 1 - P(Y = 1|\mathbf{x}) = \frac{1}{\exp(\mathbf{w}^T \mathbf{x}) + 1}$

2. $\frac{P(Y = 1|\mathbf{x})}{P(Y = 0|\mathbf{x})} = \exp(\mathbf{w}^T \mathbf{x}) \rightarrow \log \frac{P(Y = 1|\mathbf{x})}{P(Y = 0|\mathbf{x})} = \mathbf{w}^T \mathbf{x}$

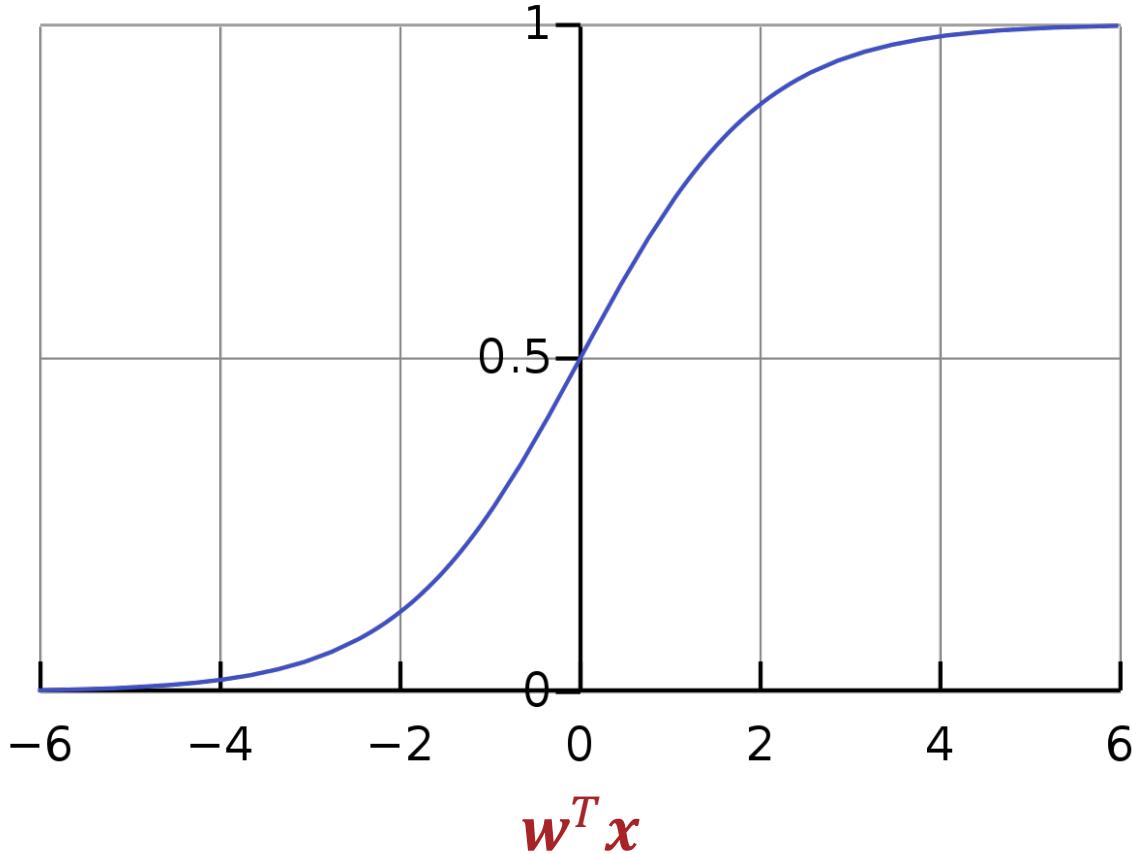

Logistic Function

$$\text{logit}(z) = \frac{1}{1 + e^{-z}}$$

Why use the Logistic Function?

logit($w^T x$)

- Differentiable everywhere
- logit: $\mathbb{R} \rightarrow [0, 1]$
- The decision boundary is linear in x !

Logistic Regression Decision Boundary

$$\hat{y} = \begin{cases} 1 & \text{if } P(Y = 1|\boldsymbol{x}) \geq \frac{1}{2} \\ 0 & \text{otherwise} \end{cases}$$

$$P(Y = 1|\boldsymbol{x}) = \text{logit}(\boldsymbol{w}^T \boldsymbol{x}) = \frac{1}{1 + \exp(-\boldsymbol{w}^T \boldsymbol{x})} \geq \frac{1}{2}$$

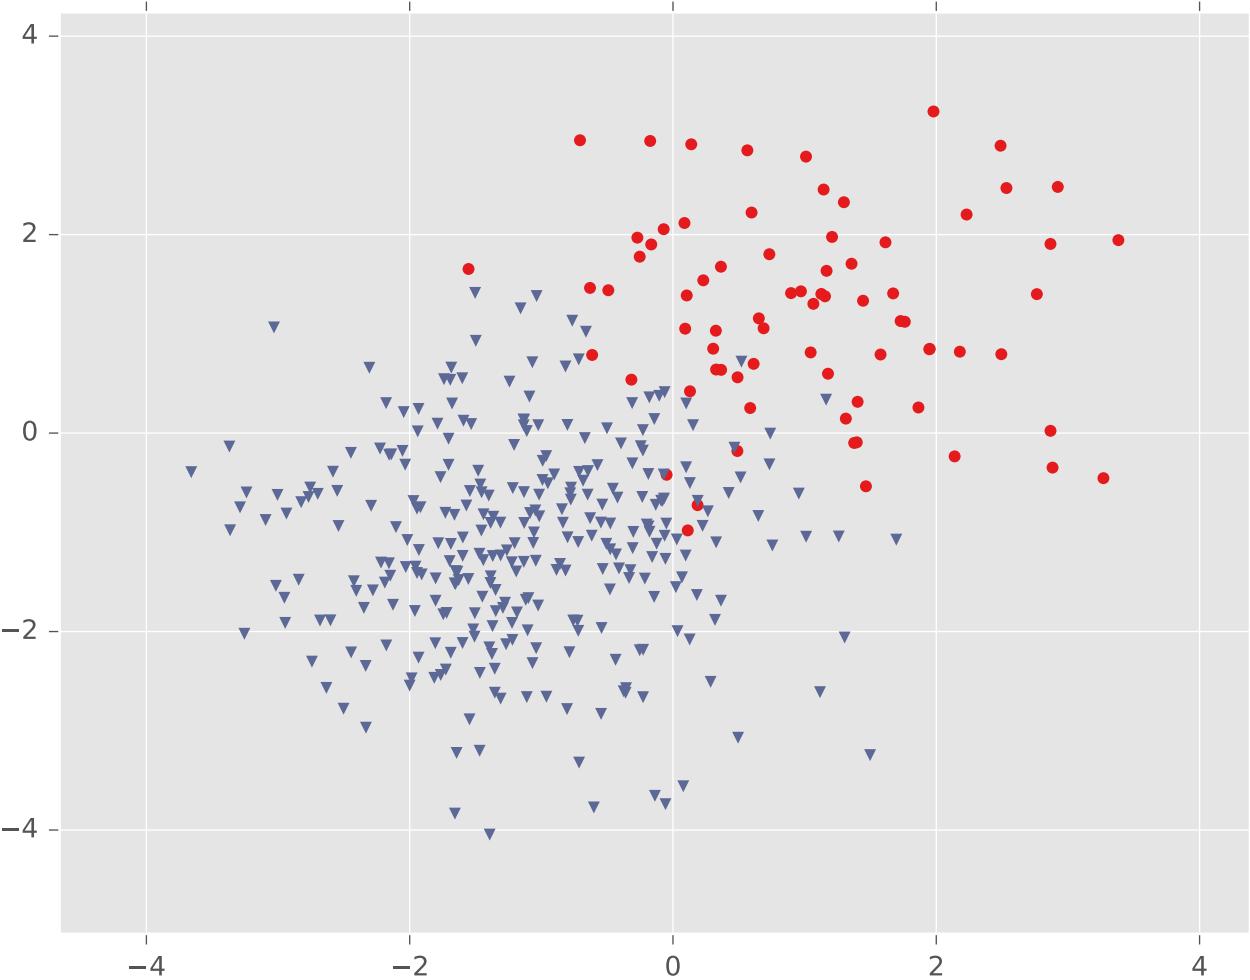

$$2 \geq 1 + \exp(-\boldsymbol{w}^T \boldsymbol{x})$$

$$1 \geq \exp(-\boldsymbol{w}^T \boldsymbol{x})$$

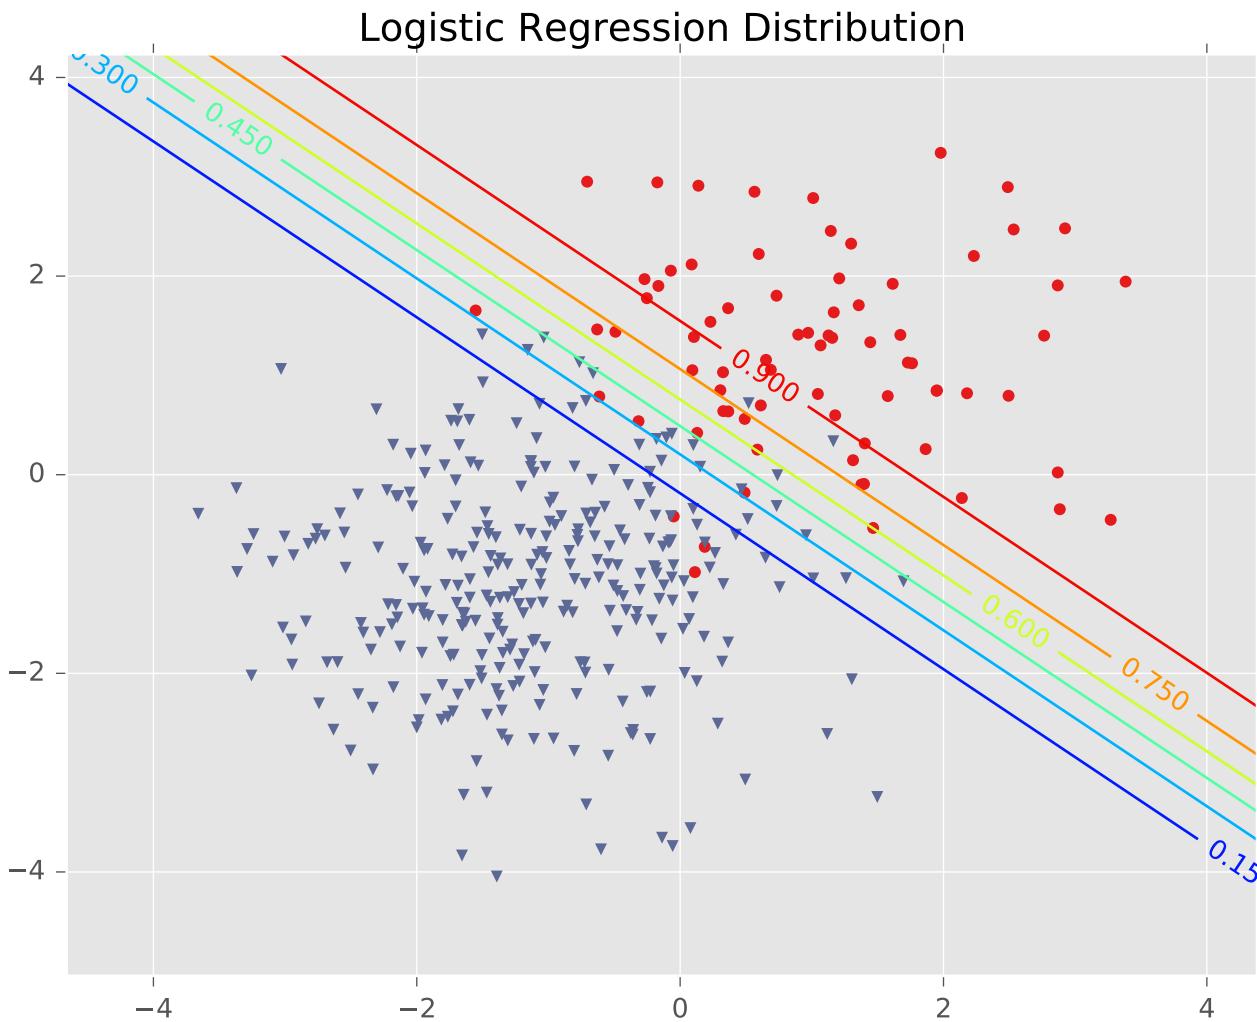

$$\log(1) \geq -\boldsymbol{w}^T \boldsymbol{x}$$

$$0 \leq \boldsymbol{w}^T \boldsymbol{x}$$

Logistic Regression Decision Boundary

Logistic Regression Decision Boundary

Logistic Regression Decision Boundary

General Recipe for Machine Learning

- Define a model and model parameters
- Write down an objective function
- Optimize the objective w.r.t. the model parameters

Recipe for Logistic Regression

- Define a model and model parameters
 - Assume independent, identically distributed (iid) data
 - Assume $P(Y = 1|X) = \text{logit}(\mathbf{w}^T \mathbf{x})$
 - Parameters: $\mathbf{w} = [w_0, w_1, \dots, w_D]$
- Write down an objective function
 - ~~Maximize the conditional log-likelihood~~
 - Minimize the negative conditional log-likelihood
- Optimize the objective w.r.t. the model parameters
 - ???

Setting the Parameters via Minimum Negative Conditional (log-)Likelihood Estimation (MCLE)

Find \mathbf{w} that minimizes

$$\begin{aligned}\ell_{\mathcal{D}}(\mathbf{w}) &= -\log P(y^{(1)}, \dots, y^{(N)} | \mathbf{x}^{(1)}, \dots, \mathbf{x}^{(N)}, \mathbf{w}) = -\log \prod_{n=1}^N P(y^{(n)} | \mathbf{x}^{(n)}, \mathbf{w}) \\ &= -\log \prod_{n=1}^N P(Y = 1 | \mathbf{x}^{(n)}, \mathbf{w})^{y^{(n)}} \left(P(Y = 0 | \mathbf{x}^{(n)}, \mathbf{w})\right)^{1-y^{(n)}} \\ &= -\sum_{i=1}^N y^{(n)} \log P(Y = 1 | \mathbf{x}^{(n)}, \mathbf{w}) + (1 - y^{(n)}) \log P(Y = 0 | \mathbf{x}^{(n)}, \mathbf{w}) \\ &= -\sum_{i=1}^N y^{(n)} \log \frac{P(Y = 1 | \mathbf{x}^{(n)}, \mathbf{w})}{P(Y = 0 | \mathbf{x}^{(n)}, \mathbf{w})} + \log P(Y = 0 | \mathbf{x}^{(n)}, \mathbf{w}) \\ &= -\sum_{i=1}^N y^{(n)} \mathbf{w}^T \mathbf{x}^{(n)} - \log(1 + \exp(\mathbf{w}^T \mathbf{x}^{(n)}))\end{aligned}$$

Setting the Parameters via MAP?

(stay tuned for
regularization,
tomorrow!)

Find \mathbf{w} that minimizes

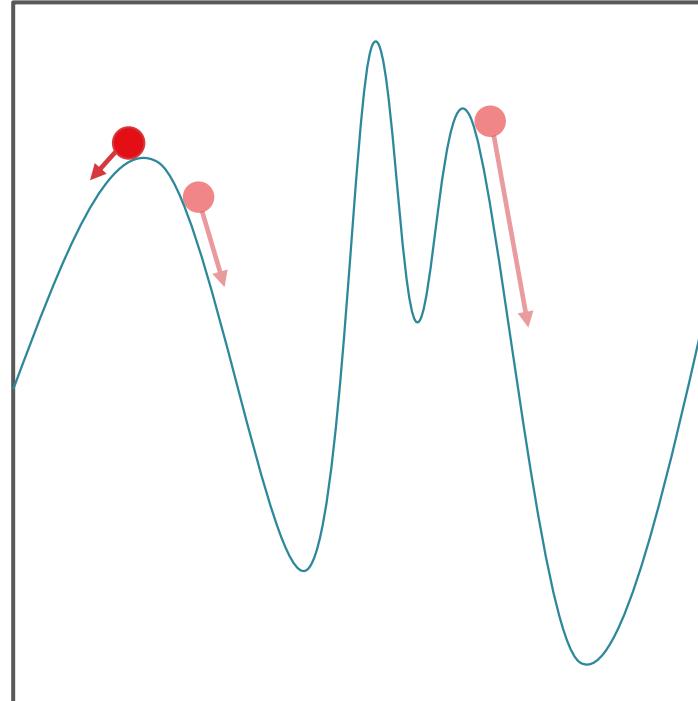

$$\begin{aligned}\ell_{\mathcal{D}}(\mathbf{w}) &= -\log P(y^{(1)}, \dots, y^{(N)} | \mathbf{x}^{(1)}, \dots, \mathbf{x}^{(N)}, \mathbf{w}) = -\log \prod_{n=1}^N P(y^{(n)} | \mathbf{x}^{(n)}, \mathbf{w}) \\ &= -\log \prod_{n=1}^N P(Y = 1 | \mathbf{x}^{(n)}, \mathbf{w})^{y^{(n)}} \left(P(Y = 0 | \mathbf{x}^{(n)}, \mathbf{w}) \right)^{1-y^{(n)}} \\ &= -\sum_{i=1}^N y^{(n)} \log P(Y = 1 | \mathbf{x}^{(n)}, \mathbf{w}) + (1 - y^{(n)}) \log P(Y = 0 | \mathbf{x}^{(n)}, \mathbf{w}) \\ &= -\sum_{i=1}^N y^{(n)} \log \frac{P(Y = 1 | \mathbf{x}^{(n)}, \mathbf{w})}{P(Y = 0 | \mathbf{x}^{(n)}, \mathbf{w})} + \log P(Y = 0 | \mathbf{x}^{(n)}, \mathbf{w}) \\ &= -\sum_{i=1}^N y^{(n)} \mathbf{w}^T \mathbf{x}^{(n)} - \log \left(1 + \exp(\mathbf{w}^T \mathbf{x}^{(n)}) \right)\end{aligned}$$

Minimizing the Negative Conditional (log-)Likelihood

$$\begin{aligned}\ell_{\mathcal{D}}(\mathbf{w}) &= - \sum_{n=1}^N y^{(n)} \mathbf{w}^T \mathbf{x}^{(n)} - \log(1 + \exp(\mathbf{w}^T \mathbf{x}^{(n)})) \\ \nabla_{\mathbf{w}} \ell_{\mathcal{D}}(\mathbf{w}) &= - \sum_{n=1}^N y^{(n)} \nabla_{\mathbf{w}} \mathbf{w}^T \mathbf{x}^{(n)} - \nabla_{\mathbf{w}} \log(1 + \exp(\mathbf{w}^T \mathbf{x}^{(n)})) \\ &= - \sum_{n=1}^N y^{(n)} \mathbf{x}^{(n)} - \frac{\exp(\mathbf{w}^T \mathbf{x}^{(n)})}{1 + \exp(\mathbf{w}^T \mathbf{x}^{(n)})} \mathbf{x}^{(n)} \\ &= \sum_{n=1}^N \mathbf{x}^{(n)} (P(Y = 1 | \mathbf{x}^{(n)}, \mathbf{w}) - y^{(n)})\end{aligned}$$

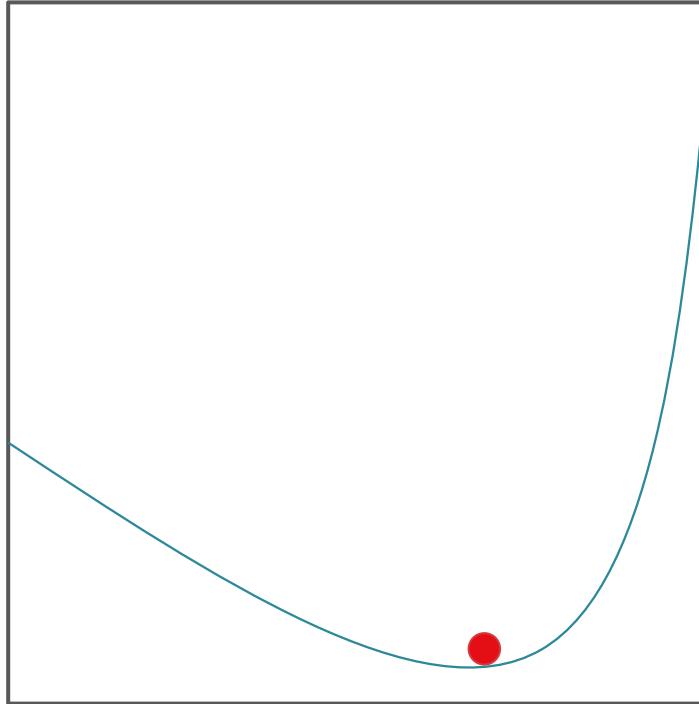

Recall: Gradient Descent

- An iterative method for minimizing functions
- Requires the gradient to exist everywhere

Recall: Gradient Descent

- An iterative method for minimizing functions
- Requires the gradient to exist everywhere

- Good news: the negative conditional log-likelihood, like the squared error, is also convex!

Gradient Descent

- Input: $\mathcal{D} = \{\mathbf{x}^{(n)}, y^{(n)}\}_{n=1}^N, \eta^{(0)}$
 1. Initialize $\mathbf{w}^{(0)}$ to all zeros and set $t = 0$
 2. While TERMINATION CRITERION is not satisfied
 - a. Compute the gradient:
$$\mathcal{O}(ND) \left\{ \nabla_{\mathbf{w}} \ell_{\mathcal{D}}(\mathbf{w}^{(t)}) = \sum_{n=1}^N \mathbf{x}^{(n)} (P(Y=1|\mathbf{x}^{(n)}, \mathbf{w}^{(t)}) - y^{(n)})$$
 - b. Update \mathbf{w} : $\mathbf{w}^{(t+1)} \leftarrow \mathbf{w}^{(t)} - \eta^{(0)} \nabla_{\mathbf{w}} \ell_{\mathcal{D}}(\mathbf{w}^{(t)})$
 - c. Increment t : $t \leftarrow t + 1$
 - Output: $\mathbf{w}^{(t)}$

Stochastic Gradient Descent

- Input: $\mathcal{D} = \{(\mathbf{x}^{(n)}, y^{(n)})\}_{n=1}^N, \eta_{SGD}^{(0)}$
- 1. Initialize $\mathbf{w}^{(0)}$ to all zeros and set $t = 0$
- 2. While TERMINATION CRITERION is not satisfied
 - a. Randomly sample a data point from \mathcal{D} , $(\mathbf{x}^{(n)}, y^{(n)})$
 - b. Compute the pointwise gradient:
$$\nabla_{\mathbf{w}} \ell^{(n)}(\mathbf{w}^{(t)}) = \mathbf{x}^{(n)} (P(Y = 1 | \mathbf{x}^{(n)}, \mathbf{w}^{(t)}) - y^{(n)})$$
 - c. Update \mathbf{w} : $\mathbf{w}^{(t+1)} \leftarrow \mathbf{w}^{(t)} - \eta_{SGD}^{(0)} \nabla_{\mathbf{w}} \ell^{(n)}(\mathbf{w}^{(t)})$
 - d. Increment t : $t \leftarrow t + 1$
- Output: $\mathbf{w}^{(t)}$

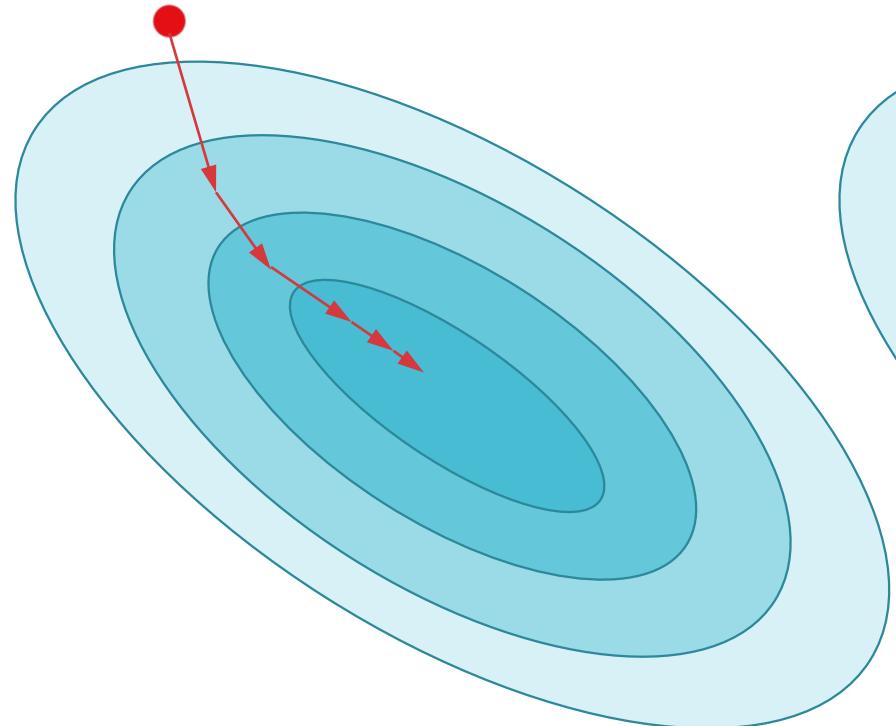

Stochastic Gradient Descent

- If the data point is sampled uniformly at random, then the expected value of the pointwise gradient is proportional to the full gradient:

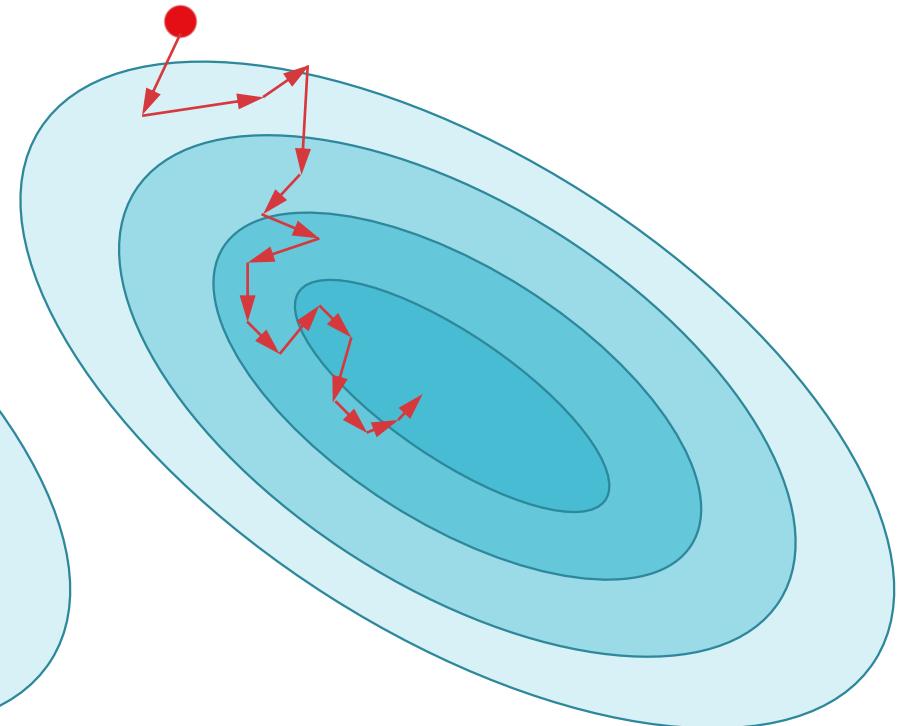

$$\begin{aligned} E \left[\nabla_{\mathbf{w}} \ell_{\mathbf{x}^{(n)}, \mathbf{y}^{(n)}}(\mathbf{w}^{(t)}) \right] &= \frac{1}{N} \sum_{n=1}^N \nabla_{\mathbf{w}} \ell^{(n)}(\mathbf{w}^{(t)}) \\ &= \frac{1}{N} \sum_{n=1}^N \mathbf{x}^{(n)} \left(P(Y = 1 | \mathbf{x}^{(n)}, \mathbf{w}^{(t)}) - y^{(n)} \right) \\ &= \frac{1}{N} \nabla_{\mathbf{w}} \ell_{\mathcal{D}}(\mathbf{w}^{(t)}) \end{aligned}$$

- In practice, the data set is randomly shuffled then looped through so that each data point is used equally often

Stochastic Gradient Descent vs. Gradient Descent

Gradient Descent

Stochastic Gradient Descent

Mini-batch Stochastic Gradient Descent

- Input: $\mathcal{D} = \{(\mathbf{x}^{(n)}, y^{(n)})\}_{n=1}^N, \eta_{MB}^{(0)}, B$
 1. Initialize $\mathbf{w}^{(0)}$ to all zeros and set $t = 0$
 2. While TERMINATION CRITERION is not satisfied
 - a. Randomly sample B data points from \mathcal{D} :
$$\mathcal{D}_{batch}\{(\mathbf{x}^{(b)}, y^{(b)})\}_{b=1}^B$$
 - b. Compute the gradient w.r.t. the sampled batch:
$$\nabla_{\mathbf{w}} \ell_{\mathcal{D}_{batch}}(\mathbf{w}^{(t)}) = \sum_{b=1}^B \mathbf{x}^{(b)} (P(Y=1|\mathbf{x}^{(b)}, \mathbf{w}) - y^{(b)})$$
 - c. Update \mathbf{w} : $\mathbf{w}^{(t+1)} \leftarrow \mathbf{w}^{(t)} - \eta_{MB}^{(0)} \nabla_{\mathbf{w}} \ell_{\mathcal{D}_{batch}}(\mathbf{w}^{(t)})$
 - d. Increment t : $t \leftarrow t + 1$
 - Output: $\mathbf{w}^{(t)}$

Key Takeaways

- Logistic regression
 - Logistic function induces a linear decision boundary
 - Conditional likelihood maximization
- Gradient descent vs. stochastic gradient descent tradeoffs
