

Lists

Organizing Data Linearly

2B

Linked Lists

15-121 Introduction to Data Structures, Carnegie Mellon University - CORTINA

1

Disadvantages of Array Lists

- If a data entry is added to or removed from an array-based list, data needs to be shifted to update the list.
- In the worst case, for an array-based list with n data entries, an add and a remove takes $O(n)$ time.
- Also, all data in the array-based list must be stored sequentially in memory. Large lists will require significant contiguous blocks of memory.

15-121 Introduction to Data Structures, Carnegie Mellon University - CORTINA

2

Singly Linked Lists

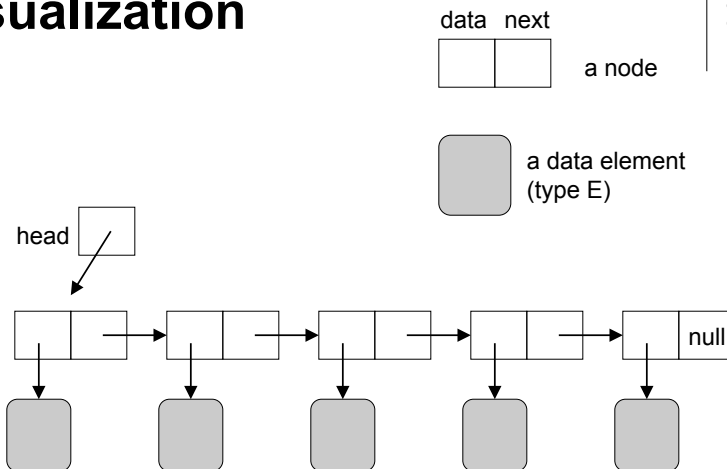

- Each **data** entry is stored in its own **node**.
- Each node has a reference to the node that contains the **next** data entry.
- A reference named the **head** points to the node with the first data entry.
- The last node in the list contains a reference of null since it does not point to any other data.
- An empty list would have a head reference equal to null.

15-121 Introduction to Data Structures, Carnegie Mellon University - CORTINA

3

Visualization

4

Inner classes

- Since a node is specific to a linked list, we will define the `Node` class to be an **inner class** of the `SinglyLinkedList` class.
- The inner class is only accessible by the class that enclosed it.
- Fields defined in the inner class are accessible by its enclosing class. (No accessors are needed.)

Node class

```
private static class Node<E> {
    private E data;
    private Node<E> next;
    private Node(E element) {
        data = element;
        next = null;
    }
    private Node(E element, Node<E> nodeRef) {
        data = element;
        next = nodeRef;
    }
}
```

Initializing an empty linked list

```
public class SinglyLinkedList<E> {  
  
    private Node<E> head;  
    private int numElements;  
  
    public SinglyLinkedList() {  
        head = null;  
        numElements = 0;  
    }  
}
```

15-121 Introduction to Data Structures, Carnegie Mellon University - CORTINA

7

Add new first list element Get size of list

```
public void addFirst(E element) {  
    head = new Node<E>(element, head);  
    numElements++;  
}  
  
public int size() {  
    return numElements;  
}
```

15-121 Introduction to Data Structures, Carnegie Mellon University - CORTINA

8

Removing the first node

```
public E removeFirst() {
    if (head == null)
        throw new NoSuchElementException();
    E result = head.data;
    head = head.next;
    numElements--;
    return result;
}
```

Traversing the list

```
public String toString() {
    String result = "";
    Node<E> nodeRef = head;
    while (nodeRef != null) {
        result += nodeRef.data + " ==> ";
        nodeRef = nodeRef.next;
    }
    return result;
}
```

Add at given index

```
public void add(int index, E element) {
    if (index < 0 || index > size())
        throw new
            IndexOutOfBoundsException();

    if (index == 0) {
        addFirst(element);
        return;
    }

    // cont'd
```

Add at given index WRONG

13

Add at given index

(cont'd)

```

Node<E> newNode
    = new Node<E>(element);
Node<E> nodeRef = head;
for (int i = 1; _____; i++)
    nodeRef = nodeRef.next;
newNode.next = nodeRef.next;
nodeRef.next = newNode;
numElements++;
    }
    
```

15-121 Introduction to Data Structures, Carnegie Mellon University - CORTINA

14

Remove at given index

```
public E remove(int index) {  
    if (index < 0 || index >= size())  
        throw new IndexOutOfBoundsException();  
  
    if (index == 0) {  
        return removeFirst();  
    }  
  
    // cont'd
```

RIGHT

15-121 Introduction to Data Structures, Carnegie Mellon University - CORTINA

17

Remove at given index

(cont'd)

```
Node<E> nodeRef = head;
for (int i = 1; _____; i++)
    nodeRef = nodeRef.next;

E result = nodeRef.next.data;
nodeRef.next = nodeRef.next.next;
numElements--;
return result;
}
```

18

Complexity

On a singly linked list with n nodes:

`addFirst` _____

`removeFirst` _____

`add` _____

`remove` _____

Disadvantages of Singly Linked Lists

- Insertion into a list is generally linear.
- In order to insert a node at an index greater than 0, we need a reference to the previous node.
- In order to remove a node that is not the first node, we need a reference to the previous node.
- We can only traverse the list in one direction.

Doubly-Linked Lists

- Each **data** entry is stored in its own **node**.
- Each node has a reference to the node that contains the **next** data entry and a reference to the node that contains the previous data entry (**prev**).
- A reference named the **head** points to the node with the first data entry and a reference named the **tail** points to the node with the last data entry.
- The last node in the list contains a next reference of null and the first node in the list contains a prev reference of null.
- An empty list would have head and tail references equal to null.
