

# UNIT 7B Data Representation: Compression

15110 Principles of Computing, Carnegie Mellon University - CORTINA

1

# Fixed-Width Encoding

- In a fixed-width encoding scheme, each character is given a binary code with the same number of bits.
  - Example:

Standard ASCII is a fixed width encoding scheme, where each character is encoded with 7 bits.

This gives us  $2^7 = 128$  different codes for characters.

15110 Principles of Computing, Carnegie Mellon University - CORTINA

#### Fixed-Width Encoding

- Given a character set with n characters, what is the minimum number of bits needed for a fixed-width encoding of these characters?
  - Since a fixed width of k bits gives us n unique codes to use for characters, where n = 2<sup>k</sup>.
  - So given n characters, the number of bits needed is given by  $k = \lceil \log_2 n \rceil$ . (We use the ceiling function since  $\log_2 n$  may not be an integer.)
  - Example: To encode just the alphabet A-Z using a fixed-width encoding, we would need  $\lceil \log_2 26 \rceil = 5$  bits: e.g. A => 00000, B => 00001, C => 00010, ..., Z => 11001.

15110 Principles of Computing, Carnegie Mellon University - CORTINA

3

# Using Fixed-Width Encoding

- If we have a fixed-width encoding scheme using
   n bits for a character set and we want to
   transmit or store a file with m characters, we
   would need mn bits to store the entire file.
- Can we do better?
  - If we assign fewer bits to more frequent characters, and more bits to less frequent characters, then the overall length of the message might be shorter.

15110 Principles of Computing, Carnegie Mellon University - CORTINA

# **Huffman Coding**

 We can use an encoding scheme named after David A. Huffman to compress our text without losing any information.

- Based on the idea that some characters occur more frequently than others.
- Huffman codes are not fixed-width.

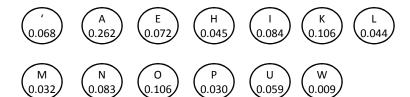

15110 Principles of Computing, Carnegie Mellon University - CORTINA

5

#### The Hawaiian Alphabet 0.068 • The Hawaiian alphabet 0.262 consists of 13 characters. 0.072 – ' is the okina which 0.045 Н 0.084 Ι sometimes occurs between K 0.106 vowels (e.g. KAMA' AINA ) 0.044 L • The table to the right 0.032 М N 0.083 shows each character along 0.106 with its relative frequency 0.030 Р in Hawaiian words. U 0.059 0.009 W 15110 Principles of Computing, Carnegie Mellon University - CORTINA

#### The Huffman Tree

- We use a tree structure to develop the unique binary code for each letter.
- Start with each letter/frequency as its own node:

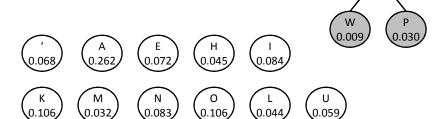

15110 Principles of Computing, Carnegie Mellon University - CORTINA

7

#### The Huffman Tree

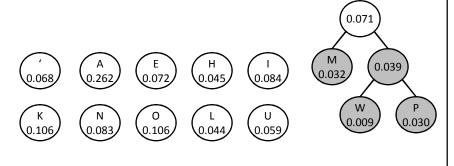

Combine lowest two frequency nodes into a tree with a new parent with the sum of their frequencies.

15110 Principles of Computing, Carnegie Mellon University - CORTINA

#### The Huffman Tree

 Combine lowest two frequency nodes (including the new node we just created) into a tree with a new parent with the sum of their frequencies.

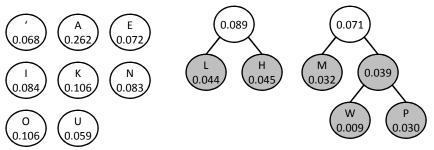

15110 Principles of Computing, Carnegie Mellon University - CORTINA

9

#### The Huffman Tree

 Combine lowest two frequency nodes (including the new node we just created) into a tree with a new parent with the sum of their frequencies.

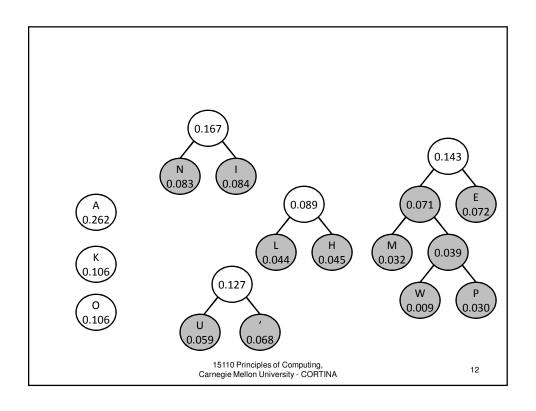

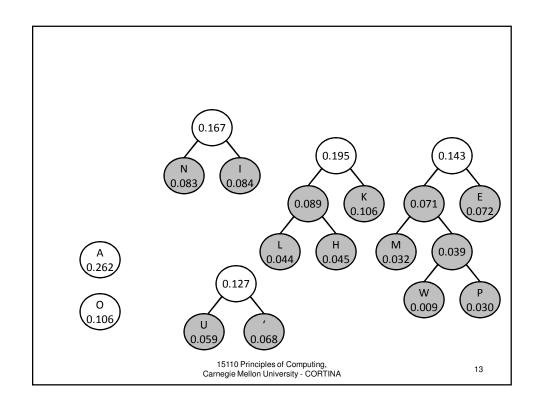

15110 Principles of Computing, Carnegie Mellon University - CORTINA

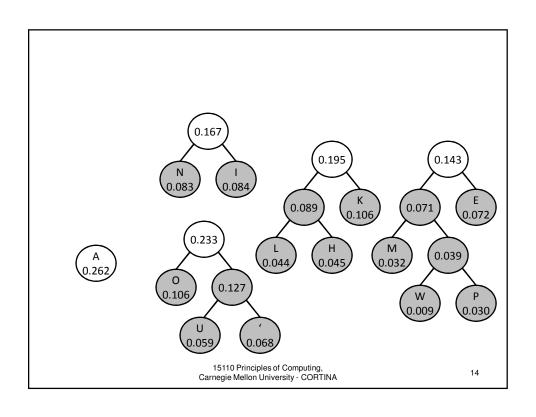

### The Huffman Tree

 Combine lowest two frequency nodes (including the new node we just created) into a tree with a new parent with the sum of their frequencies...

# **Priority Queues**

NOTE: For this unit, you will need RubyLabs set up and you will need to include BitLab (see p. 167)

A priority queue (PQ) is like an array that is sorted.

```
pq = PriorityQueue.new
=> []
```

 To add element into the priority queue in its correct position, we use the << operator:</li>

```
pq << "peach"
pq << "apple"
pq << "banana"
=> ["apple", "banana", "peach"]
```

15110 Principles of Computing, Carnegie Mellon University - CORTINA

23

# Priority Queues (cont'd)

 To remove the first element from the priority queue, we will use the shift method:

```
fruit1 = pq.shift
=> "apple"
pq
=> ["banana", "peach"]
fruit2 = pq.shift
=> "banana"
pq
=> ["peach"]
```

15110 Principles of Computing, Carnegie Mellon University - CORTINA

#### **Tree Nodes**

We can store all of the node data into a 2-dimensional array:
 table = [ "'", 0.068], ["A", 0.262],

```
["E", 0.072], ["H", 0.045], ["I", 0.084], ["K", 0.106], ["L", 0.044], ["M", 0.032], ["N", 0.083], ["O", 0.106], ["P", 0.030], ["U", 0.059], ["W", 0.009]]
```

 A tree node consists of two values, the character and its frequency. Making one of the tree nodes:

```
char = table[2].first # "E"
freq = table[2].last # 0.072
node = Node.new(char, freq)
```

15110 Principles of Computing, Carnegie Mellon University - CORTINA

25

# **Building a PQ of Single Nodes**

```
def make_pq(table)
    pq = PriorityQueue.new
    for item in table do
        char = item.first
        freq = item.last
        node = Node.new(char, freq)
        pq << node
    end
    return pq
end</pre>
```

15110 Principles of Computing, Carnegie Mellon University - CORTINA

# **Building our Priority Queue**

```
pq = make_pq(table)
=> [( W: 0.009 ), ( P: 0.030 ),
      ( M: 0.032 ), ( L: 0.044 ),
      ( H: 0.045 ), ( U: 0.059 ),
      ( ': 0.068 ), ( E: 0.072 ),
      ( N: 0.083 ), ( I: 0.084 ),
      ( K: 0.106 ), ( O: 0.106 ),
      ( A: 0.262 )]
      This is our priority queue showing the 13 nodes in sorted order based on frequency.
```
